Almost all the features that go to the making of a happy home have been considered and are too numerous to be considered separately here. The following are among the more important of the general observations that arose as a result of the inquiry. The needs and wants of the people are so varied that it will be impossible to satisfy everyone. On the whole, people are attached to their present homes and, although they grumble, would be prepared to make the best of a bad job if the glaring faults of their houses were put right. In many cases, the addition of a bathroom or a hot-water system would be enough to make the householder contented with her lot, while an extra cupboard in the kitchen or a modern labour-saving range instead of the old-fashioned coal ranges would be enough to satisfy other people.

The houses-versus-flats controversy is given the blow which should knock it out as the favourite artificially introduced subject for discussion groups. The mass of the people still prefer to live in a small house or bungalow with a garden; the garden city or housing estate has particular appeal. "Yet good and well-built flats, near people's work place, are suitable for some, and are appreciated particularly if they incorporate amenities such as constant hot water, lifts and playgrounds for children. At present, the choice is usually between a house and a garden a long way away from the work place and a flat reasonably near work. If people could, without having long journeys to work, live in a house of their own, the majority would infinitely prefer it."

Another point that needs scrutiny is that the younger people tend to be much more discontented with their lot than older people, while nutritionists will not be surprised to read that people are very reluctant to alter their feeding habits even in the face of acute food shortage.

The most disquieting feature of the report is an observation which is revealed indirectly rather than as answers to leading questions. In attempting to find out how much people liked the neighbourhood in which they live, the interviewers were astonished to find that "less than one person in a hundred mentioned any activity that involved co-operation with their fellow-citizens. The idea of living in a neighbourhood thus appears to have virtually no connection with any responsibility for its good government in the mind of the average housewife. There was no single reference to political activities, practically none to any local authority except in so far as it was a landlord and only a few to various forms of social, cultural and religious activity." If we accept the idea that the basis of democracy lies in the mutual responsibility of a community and all the individuals composing it, it would appear that we have a long road to travel before the idea is put into practice in Great Britain.

(2) Mr. Madge's book deals with an inquiry made into the way that spending and saving have changed during the War. The methods used were similar to those adopted by Mass Observation, but differed from them in the use of a much smaller team of interviewers. Surveys were carried out in the cities of Bristol, Glasgow and Leeds, additional material being provided by the actuary of the Aberdeen Savings Bank.

The investigation began as an attempt to find out how much of their income was being saved by wage-earner families by asking a random sample of them a number of direct questions about their savings. Because of tendencies to conceal some forms of saving from the questioner, the results proved unsatisfactory.

The inquiry was then extended to obtain particulars of spending as well as saving. It was thus possible to see whether the account given balanced with what was known of the family income.

The interviewing was carried out in an extremely thorough manner, and eventually reached a high point of efficiency. Of special interest in the general conclusions is one observation which keeps obtruding itself. While saving was shown to vary greatly among individuals, it became clear that a large proportion of wage-earners' savings are due to a small proportion of wage-earners. It is evident that, after the War, this must mean that the small proportion of wage-earners with a strong propensity to save will emerge as a special group with special interests, considerably richer than their fellows. This group, which has been steadily increasing during the past fifty years, is likely to develop even greater political significance in the future.

Another interesting conclusion which is presented in the report is that the average husband keeps roughly a quarter of his earnings as pocket money. The retention of such a large share of his earnings may be due to the husband's desire to indulge his own psychological inclinations towards the act of spending.

The report is rounded off by two appendixes, which have been prepared by Erwin Rothbarth. One contains a note on a method of determining income for families of different composition and the second an estimate of national savings per family and the relation of saving to income and excess income. They add to the value of a report which would still be of great value without them. Mr. Madge and his team are to be congratulated on an admirably executed investigation in the difficult field of social economics. T. H. HAWKINS.

MICROBIOLOGY OF THE AIR

Aerobiology

Edited by Forest Ray Moulton. (Publication of the American Association for the Advancement of Science, No. 17.) Pp. x+289. (Washington, D.C.: American Association for the Advancement of Science, 1942.) n.p.

ALTHOUGH it is fully sixty years since the classic work of Tyndall and of Miquel on air-borne micro-organisms and twenty-five years since Molisch coined the word 'aeroplankton', this is the first book in any language which attempts to deal with the microbiology of the air in any comprehensive way; and this in spite of the intensive interest in every aspect of atmospheric study which the development of aviation has created.

It is the outcome of a symposium at a meeting of the American Association for the Advancement of Science, held in September 1941, organized by the Section of Medical Sciences of the Association, and it clearly bears the imprint of its medical origin. Among the fifty-five contributors no fewer than thirty-eight are either medical men or else represent medical institutions, and twenty-eight out of the thirty-seven papers included deal with either air-borne infection or with aerial allergens. This seems to mark a significant swing back towards the view of the early antiseptic surgeons and the Flugge school, to whom air-borne infection seemed all-important, but it is a return well guarded by a stricter ascertainment of facts and by their more precise application.

No one can overlook the importance of the medical aspects of aerobiology. Sir Leonard Hill has said that man has learned by painful experience to safeguard the purity of his food and of his drink, but has still to learn to take the same precautions for the air he breathes. Yet it must be admitted that the strong medical bias of the book detracts somewhat from its general scientific consequence. There are so many purely scientific problems left aside in favour of special medical topics. For example, the methods of killing air organisms loom so largely in the contents that one is tempted to make the rude suggestion that "Aeronecrology" might have been a better title.

If this is, therefore, not quite the book for which the scattered workers in this field have hoped, if it falls a little short of epoch-making, it is nevertheless a very considerable work. Its importance lies in its value as a summary and review as well as in the new information presented. Naturally, recent American work is most fully covered, but earlier European work is somewhat imperfectly recognized and not always correctly. It is not true to say, for example, that high-altitude collections were first made by aeroplane. Christiani, Flemming and Martin Hahn all made extensive collections from free balloons before the day of the aeroplane.

We have still a very imperfect idea of the aerial flora. There has been a vast deal of ingenuity expended on devices for the capture of aerial organisms, but there is as yet no wholly satisfactory, quantitative instrument for that purpose. Electrostatic precipitation may be 100 per cent physically efficient, but it is very difficult to apply in the field and it seems to kill the organisms precipitated. No washing or filtration method is anything like perfect, and even the impingement or the centrifugal methods, which are probably the best at our disposal, are each deficient in some particular. This may explain why so much reliance is still placed upon primitive deposition methods with agar plates, but it does not excuse us for trying to found quantitative conclusions upon such demonstrably faulty practice.

The results of air collections have hitherto been too often stultified by another factor, namely, very limited conditions of culture. Beef or malt agar at 37° C. or 25° C. represent almost the whole range of conditions employed, and there is a total lack of statistically controlled analysis of variance with medium, time and temperature, such as the soil bacteriologists have used. This is a general criticism but it is not without a present application.

It need scarcely be said, therefore, that our knowledge of specific distribution, association and bionomics is well-nigh nothing. With few exceptions the ecological outlook on air problems is missing both in the present work and elsewhere. The aeroplankton as a whole is treated as temporary, like the pollen grains and the fungal spores, and the air is viewed simply as an agent of transport, even for the bacteria and yeasts. "Dust to dust" seems to be the only cycle envisaged. Yet the experiments of Trillat and others show at least the possibility that the air may be a vegetative habitat, and the large proportion of non-spore-formers present, which anyone may easily verify, needs more than a conventional explanation, unless we are to go back to the idea of 'germs', in the original Tyndallian sense.

The material in the book is treated under two main headings: "Extramural" and "Intramural".

Under the first heading, Stakman gives a survey of air-transport problems. Wodehouse provides some fine and useful plates of pollen forms and Durham treats of mould spores as allergens. Proctor and Parker give a summary of the work, mainly by the former, on high altitude collecting. ZoBell gives some interesting new information on bacteria in marine air, emphasizing the overlooked condition of halophily prevalent among them and incidentally putting an end to the myth of the sterility of oceanic air masses, on which the belief in the terriginous origin of all aeroplankton largely rests.

Keitt and Christensen give good reviews of local and distant transportation of plant pathogens. Lastly, Glick's account of the admirable aeroplane studies of insect distribution, under the care of the U.S. Department of Agriculture, whet the appetite for more facts about this infant science, which may become of such immense significance in the aerial age before us.

Under the heading of "Intramural", Wells and Wells introduce the papers included as laying the foundation of a general theory of air-borne infection. The series is comprehensively planned. It covers first the physics of microscopic particles in air suspension (Hatch, Jennison and Phelps). Secondly, there are fifteen papers on air disinfection, treating particularly of ultra-violet radiation in many aspects. Thirdly, there are six papers on the environmental control of air infection both for adults and infants and four papers of observations on the actual passage of air-borne infectants. Finally, there are two papers on the use of aerosol mists as disinfectants. The relative simplicity and effectiveness of this method, especially with propylene glycol, entitles it to greater prominence.

Incidentally, British readers will be interested in the revelation that very large stocks of cellulose acetate masks have been prepared in Great Britain for issue as safeguards in the event of serious shelter epidemics appearing. Happily they have not been needed.

Notwithstanding the regrets which have been expressed that a more all-round treatment of the subject has not been possible, the reviewer would pay high tribute to the workers concerned in producing this attractive and important book. Such an amount of modern work has here been brought together and reviewed by first-hand authorities that it is quite indispensable to all who are interested in the microbiology of the atmosphere. We may well end by submerging criticism in admiration.

R. C. McLEAN.

AMERICAN TIMBERS

Commercial Timbers of the United States

Their Structure, Identification, Properties and Uses. Published formerly under the title "Identification of the Commercial Timbers of the United States". By Prof. H. P. Brown and Prof. A. J. Panshin. (American Forestry Series.) Pp. xxi+554. (New York and London: McGraw-Hill Book Co., Inc., 1940.) 35s.

A MORE suitable title for this book than that selected by the authors would have been "A Treatise on Wood Growth and Structure". The reader will find that out of 554 pages only 154 can be said to be informative on the subject of commercial timbers of the United States: these 154 pages include seventy-five kinds of woods, on which the information is limited and generally highly technical. The uses of the timbers named are drawn only from information within the United States, and a glance at the bibliography displays perhaps a somewhat insufficient research.

A treatise on the commercial timbers of the United States should not neglect the commercial aspect. The highly organized methods employed by American commercial men have played an important part in the export trade to every part of the world. The total import into the United Kingdom alone for the year 1938 amounted to no less than £3,672,747, and of oak alone to 5,841,395 feet cube, valued at £1,038,839—by no means a negligible matter.

American timbers will be met with all over the globe. The traveller in India and Burma may find himself in a railway carriage lined with American timber, and even in the most remote districts of Burma housewives may be seen using domestic articles made from American woods. None of these interests, however, is mentioned in the work before us. From a commercial point of view, therefore, the reader is left unsatisfied.

There seems to be a certain lack of clarity as to the aim of the book. In the introduction Mr. Walter Mulford says: "The American Forestry Series is intended for the college student, the practising forester, and men in the forest industries", and in a somewhat confusing manner he informs the public that "Forestry is a profession", modified later by a further statement that it "is not an exact profession", and again that "Forestry is not a science", summing up that "The American Forestry Series is to be professional in character, with as much sound science as it is possible to include". The distinction between a "profession" and an "exact profession" is difficult to understand, as also what is meant by "sound science". The claim that "Forestry is not a science" might be open to dispute. Nature has provided a wealth of forests for the enjoyment and use of mankind, and for the necessary health and safeguard of climate and soil, but this is so far as the natural forest carries us. It is clear that the science of controlling and perfecting the man-made forest has become a necessity as a result of the demands of civilization; but while the problem is interesting, the subject is beyond the scope of the present work.

Attention having been directed to certain matters in which the book fails to supply information that might well be expected, it is pleasant to be able to commend many merits which it does undoubtedly possess.

When we come to the subject of wood growth and structure, quality and texture, the origin of wood, its gross features, its woody plant cells, minute structure, and miscellaneous information, the authors are at home, and have contributed an excellent treatise for the instruction of the forest student and the ordinary reader. Two hundred and ninety pages are devoted to these subjects, presented in clear and concise terms, and fully illustrated by two hundred and twenty photomicrographs and forty-eight plates, which include representations of the timbers as they are severally constructed and as they appear when adapted to domestic use.

ALEXANDER L. HOWARD.

Elementary Structural Analysis and Design

Steel, Timber and Reinforced Concrete. By Dr. Linton E. Grinter. Pp. xiii+383. (New York: The Macmillan Company, 1942.) 18*s*. net.

THEORY of structures is, by general consent, a necessary subject in the curriculum of the engineering student; there is, however, considerable divergence of opinion as to the extent to which it should be supplemented by the study of design. The reason is clear: successful design calls for far more than the student can acquire within the university. There is, however, real value in giving him some training in the technique of design, and Dr. Grinter is to be congratulated on the admirable way he has presented this difficult subject.

Only the simplest basic theory is used; for example, redundant structures are reduced to statically soluble cases by suitable simplifications, and the actual numerical calculations are, therefore, easy. One of the most attractive features is the series of design sheets which so fully illustrate the book and which teach the student, by example, the importance of a logical and neat lay-out of calculations. The contents include excellent chapters on welded construction and on construction in timber, in addition to the more usual subjects.

The author naturally deals with American practice, and in a few instances the British student will observe differences; for example, a reversal of the conventional signs for bending moments and shearing forces and the fact that the Perry-Robertson strut formula, so widely used in Britain, is replaced by the secant formula. These and differences in detail design, however, add to the interest.

The book is clearly and attractively written and can be thoroughly recommended to any student as complementary to his study of theoretical structures. He is difficult to please if he does not read it with enjoyment as well as benefit.

A. J. S. PIPPARD.

An Introduction to the Modern Theory of Valency

By Dr. J. C. Speakman. Second edition. Pp. 159. (London: Edward Arnold and Co., 1943.) 5*s*. 6*d*. net.

IN this book the author conducts his readers carefully and pleasantly through the complex maze of valency problems. Particularly valuable, in the reviewer's opinion, is the discussion of polar and nonpolar compounds in Chapter 9 in terms of characteristic properties like dielectric constants, association and so forth. A very fair and reasonable balance is held between the views of the leading authorities, and thus the student is encouraged to use his analytic and critical faculties as his own knowledge progresses.

So far so good. But the fact has to be faced sooner or later (and that it is not faced here and now is by no means Dr. Speakman's fault) that a real comprehension of the *modern theory* of valency demands mathematical ability and equipment of an order probably altogether different from that envisaged in the average physico-chemical laboratory. It is thus just worth pondering whether 'descriptive' books on the subject are wholly justified these days. If they are, the present one is an excellent example of what can be done. On the other hand, there seems a certain awareness in these pages that all is not plain sailing: maybe a mathematical appendix to help bridge the gap and point out the heights beyond might remove some heart-searchings on this score.

F. IAN G. RAWLINS.

School Physics

By T. M. Yarwood. Part I. Pp. xii+366. (London: Macmillan and Co., Ltd., 1943.) 5*s*.

THIS book contains the work for the first two years of a four-year concentric course in physics up to School Certificate standard. The remaining two years' work is to be dealt with in a second volume.

Although there are many books already available which fulfil the same purpose, this one will have a good reception. There is nothing new in the presentation of the principles; its difference lies in the many descriptions of modern appliances and the references to the applications of physics in everyday life. Many of these are too complicated for the younger boy but, as the author points out, much can be omitted from the first reading and left until the School Certificate year, when both Parts I and II should be used.

The book is attractive. It is well set out and has an abundance of good diagrams. The modern applications will appeal to the boy and, what is of paramount importance, attract him to read the book out-of-school. There are many references to aeronautics, and war-time publication is marked by the inclusion of descriptions of modern creations such as the barrage balloon.

The style is good, but a boy of eleven may find the language a little too difficult. The examples, which are collected at the back, are not very numerous but nevertheless sufficient. It is disappointing that the few extra topics required for the physics section of the General Science syllabus are not included, for, with such additions, the book would have the much wider appeal it justly deserves.

On Pseudohypertrophic and Allied Types of Progressive Muscular Dystrophy

By Julia Bell. (Being Part 4 of Vol. 4, "Nervous Diseases and Muscular Dystrophies", of "The Treasury of Human Inheritance".) Pp. iv+283–342+plates 33–44. (Cambridge: At the University Press, 1943.) 12*s*. 6*d*. net.

DR. JULIA BELL has contributed a useful monograph on muscular dystrophy in man to "The Treasury of Human Inheritance" series. Clinical and genetical data from more than 1,300 individuals exhibiting this distressing abnormality are analysed in regard to mode of inheritance, prognosis, symptoms, fertility and time of onset. She divides the clinical types into three groups but points out that intergrading may occur. Each group on the whole persists in one family and is partly related to one of three genes which behave as dominant, recessive or sex-linked respectively. Several problems relating to development and transmission of the abnormality are discussed.

Dr. Bell points out that if 140 individuals had abstained from parenthood, there would have been a reduction of 468 dystrophic and 1,195 apparently normal individuals. Of these the members of the dominant gene group live long and may produce a proportionately large number of dystrophic and normal non-carrier individuals, while the affected members of the sex-linked group have a short life and will not affect the future generations to any great extent. The publication of such analytical résumés as this by Dr. Bell is of great value to science and medicine.

F. W. SANSOME.

PHOTOGRAPHIC ANALYSIS OF MOTION*

By E. R. DAVIES

Kodak Research Laboratories

TO-DAY we turn naturally to photography to analyse movements which are too rapid for our eyes to follow. If we tend to take this powerful weapon too much for granted, it must be remembered that there were formidable experimental difficulties facing the investigator before the advent of photography. Marey, while director of the Physiological Station in Paris, devised a most ingenious way of studying the movements of a horse. Pressure chambers fitted to the underside of the horse's hooves were connected by pneumatic tubes to a recording mechanism held by the rider, which registered the time of duration of contact of each hoof with the ground. Marey did much painstaking work along these lines between 1860 and 1880.

Muybridge, a native of Kingston-on-Thames, was conducting a photographic survey of the Californian coast in 1872 when he was appealed to by Governor Sandford to settle a controversy which was raging in San Francisco and which was aroused by Marey's analysis of the movements of a horse. The question was whether a trotting horse ever had all its feet free of the ground simultaneously. Muybridge set himself the task of obtaining photographic proof and achieved immediate success. He used a camera fitted with what may be loosely described as an instantaneous shutter and, taking photographs at random, soon obtained one which showed all the horse's feet free from the ground. The controversy was settled; but, more important, the direction of Muybridge's life's work was settled also.

For the exhaustive investigation of animal locomotion, upon which he soon embarked, Muybridge erected an elaborate apparatus on the racecourse at Palo Alto, near San Francisco. A battery of twenty-four cameras was arranged along one side of the track. Across the track was stretched a number of threads each connected to the shutter on one of the twenty-four cameras. The camera shutter was in the form of a guillotine urged downwards by a spring, and was released by an electro-magnetic relay on the breaking of the thread. In this way, as the horse passed in front of the cameras, it broke the threads in succession, and a series of instantaneous photographs was obtained. The time of exposure given by the shutters was of the order of 1/1,000 sec., and it is remarkable that Muybridge was able to obtain sufficient exposure with the photographic materials available to him. This was the time of the wet-plate process, and, compared with modern practice, photography was laborious in the extreme. To obtain sufficient exposure, Muybridge arranged a sloping white background to catch the light of the sun. Against this the horse stood out in sharp relief. Even so, his early results were mere silhouettes lacking all detail. With the increasing use of the gelatin dry plate (invented by Maddox in 1871), the photographic process was greatly simplified, and the sensitivity to light was increased many times. In his later work, Muybridge was thus enabled to obtain photographs showing detail. An impression of the scale of his operations will be gained from the statement that he exposed no fewer than 100,000 plates in the two years, 1884 and 1885.

Muybridge showed how the pictures taken successively by his battery of cameras could be combined to reproduce the appearance of the original movements. He printed his negatives in order on a band of paper. One of his original records was presented to the Royal Institution following the discourse he gave in 1882. The record, which is still preserved at the Institution, is placed in an apparatus known as a zoetrope, which is simply an empty cylinder with vertical slots arranged at equal intervals around the circumference, and it is carried on a vertical axis. On rotating the cylinder the pictures are viewed in succession through the slots and appear to be in motion. Muybridge thus raised a toy of the Victorian drawing-room to the status of a scientific instrument, and used it to demonstrate the correctness of his method of photographic analysis. The zoetrope, and other improved designs for which he was responsible, may be rightly regarded as forerunners of the modern cinematograph projector.

The cinematograph projector and camera were brought a stage closer by Marey, who, in his chronograph, employed a band of film on which successive photographs were taken, and who devised another apparatus for viewing the results by projection on a screen. Marey was a most remarkable man. I have already mentioned his work with pressure chambers and pneumatic tubes. Introduced to the photographic method by Muybridge, he was quick to seize upon its possibilities. His book "Le Mouvement" (published in 1894) reveals him as a brilliant experimentalist. His investigations covered the analysis of the locomotion of many animals, of birds in flight, of insects and even of micro-organisms by means of photography under the microscope. Few developments in high-speed photography were not visualized, and in some part realized, by him.

As typical of his work, I will single out for mention one technique which has proved of lasting value. Marey built a camera in which the shutter was a disk with radial slots. This revolved in front of the camera lens and caused a series of photographs to be taken in rapid succession on the same plate. In place of Muybridge's brilliantly lit background against which the moving object was revealed as a silhouette, Marey used a black background and whitened his object. In this way only the object (and not the background) was recorded during the successive exposures of the plate.

Marey's rotating disk shutter with its radial slots gave individual exposures of about 1/25,000 sec. This was an advance on Muybridge's shutter time of 1/1,000 sec., but is nevertheless far too long a time for many purposes. Mechanical shutters of any type have obvious limitations due to the inertia of the moving parts. But the problem can be approached from a different angle. It will be obvious that the desired result will be obtained if the camera shutter is left open and the subject illuminated instantaneously. Light flashes can be obtained of extremely short duration, and their use in 'stopping' rapid motion represents a milestone in the road of progress.

Lord Rayleigh used magnesium powder for a slow flash, and the electric spark for a fast flash with a time of duration of the order of one millionth of a second. With this he was successful in photographing a soap film in the act of disrupting—a phenomenon that takes place with extreme rapidity.

---

* Substance of a Friday discourse delivered at the Royal Institution on December 11, 1942.

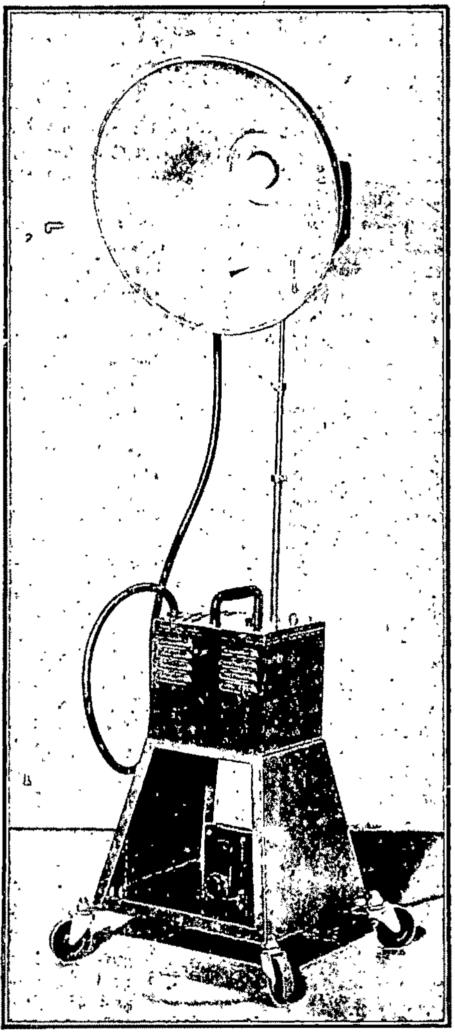

Fig. 1. KODATRON SPEED LAMP.

Prior to this time Worthington had used the electric spark in his beautiful experiments on the formation of drops and the mechanism of splashes[*]. His early work was not photographic. He observed different phases of the splash made apparently stationary by the light of the flash, and sketched what he saw. For his later investigations on surface tension phenomena he used photography.

The electric spark is fast enough to permit the photography of projectiles in flight. Sir Charles Boys took such photographs around 1890. They were shadow photographs; no camera or lens was used. The bullet passed between the photographic plate and the spark, and thus cast the shadow. In front of the plate, and in the line of flight, were two wires forming a gap in series with the spark gap. As the bullet bridged the gap, the fall in the resistance of the circuit caused the spark to pass and the photograph was obtained. Many associated phenomena are clearly revealed in such photographs. The nose of the bullet forms a bow wave. This travels with the speed of sound in air, about 1,100 ft./sec., and Boys showed how the speed of the bullet can be calculated from the angle between the bow wave and the line of flight. The bullet, though travelling at more than twice the speed of sound, is revealed with extreme sharpness by the spark, which lasts for less than one millionth of a second. Boys succeeded in measuring the duration of his spark by reflecting it on to a photographic plate by a rapidly revolving mirror and measuring the length of the trace—a method which we still use to-day.

Boys' projectile photographs bear comparison with the most modern work. The chief difference seen in the beautiful photographs published by Quayle of the Bureau of Standards in 1925 is the absence of the synchronizing wires. Quayle fired his spark by means of a microphone actuated by the noise of the explosion. This method was suggested by Dr. Mach of Vienna, whose father, Prof. Mach of Prague, was the first to obtain photographs of bullets in 1881. Mach, however, was not able to realize this method of synchronization with the apparatus available to him.

So much for the early history of the subject. By the turn of the century the principles of photographic analysis of motion were well understood: the possibilities of the method were fully realized. Advance since that time is largely a story of improvements in technique: improvements in photographic materials, in light sources and, above all, in the development of the cinematograph.

As to photographic materials, it is a story of steady improvement in quality and advance in sensitivity. I thought we had nearly reached finality a few years ago; but the War has brought forth a tremendous effort, and the fastest materials to-day are several times as sensitive as they were only two or three years ago. At a guess—it is little more in the absence of precise data—I should say that since Muybridge's time we have seen an increase of at least a hundred times in the speed of photographic materials. That is to say, we can achieve similar results to-day with 1/100th of the light.

Lenses, too, have improved out of all knowledge. But here again it is difficult to give a precise figure for the effective increase in speed, for the very fast Petzval portrait lens was introduced in 1840—within a year of the invention of photography. However, it was poorly corrected, and a common aperture in those days was $f/8$. To-day $f/1 \cdot 5$ is equally common—an increase in light-gathering power of thirty times.

To turn to light sources: the spark is an admirable way of obtaining extremely short exposures, and is probably unsurpassed when exposures of less than a millionth of a second are required. Apart from projectile photography, however, such extremely short exposures are rarely needed. A large output of light is more often desirable, and the possibilities of the spark in this direction are severely limited.

Recent developments of the gas discharge tube have resulted in a much more generally useful source of light. For the cold

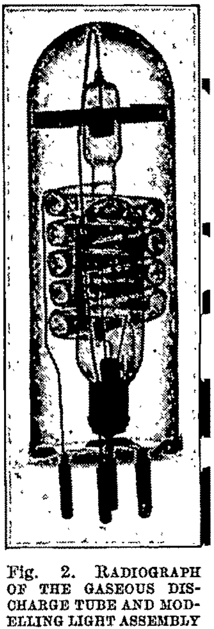

Fig. 2. RADIOGRAPH OF THE GASEOUS DISCHARGE TUBE AND MODELLING LIGHT ASSEMBLY FROM THE KODATRON SPEED LAMP. THE DISCHARGE TUBE IS WOUND ROUND THE TUNGSTEN FILAMENT LAMP WHICH IS USED FOR ARRANGING THE LIGHTING ON THE SUBJECT. NOTE (AT THE LEFT) THE TRIGGERING ELECTRODE PASSED ROUND THE COILED DISCHARGE TUBE.

---

[*] Worthington, A. M., "The Splash of a Drop and Allied Phenomena" (*Proc. Roy. Inst.*, May 18, 1894): "A Study of Splashes" (London, 1908).

cathode discharge tube, which represents a most important advance, we are largely indebted to Edgerton, of the Massachusetts Institute of Technology. A commercial version of the cold cathode discharge tube is the Kodatron Speed Lamp (Figs. 1 and 2). This consists of a discharge tube wound in the form of a helix to give a compact source of light, with a frosted glass container and a reflector. The tube is filled with a mixture of rare gases at low pressure and provided with anode and cathode. The Kodatron is self-contained, with a control box in the base of the stand supporting the reflector. On connecting with the 240 volt A.C. supply and switching on, a bank of condensers is charged to 2,000 volts. Nothing happens, since the gas pressure is adjusted to withstand this potential. The tube contains, however, a third electrode and, on depressing a second switch, this conveys a high-frequency pulse to the tube. The gas is ionized; the sparking potential drops to below 2,000 volts; the current passes between the electrodes and is accompanied by a vivid flash of light. The duration of the flash depends upon the condenser capacity. Using the full capacity of 112 mfd., the flash lasts for 1/5,000 sec. Within the angle of the reflector the luminous output is of the order of 50 million candle-power; and with a fast film and high-aperture lens, photographs can be taken of objects at a distance of 100 yd. from the lamp.

As this lamp demonstrates, electronics have played their part in the advance in the design of light sources. The application of electronics has also enormously simplified the problems of synchronization. If a beam of light is caused to fall upon a photo-electric cell, the cutting of the beam can be made to fire the flash. A microphone connected with the Kodatron illustrates the principle of synchronization by sound. By varying the distance between the microphone and the source of sound, a time lag can be introduced to the extent of 1/1,000 sec. per foot. This is often convenient in projectile photography. The spark can be fired at any predetermined interval of time after the explosion and the bullet thus photographed at any required distance from the muzzle.

Dr. Slack, of the Westinghouse Laboratories, has recently devised an X-ray tube which does not contain a heated filament to provide the source of electrons. It functions in much the same way as Edgerton's cold cathode discharge tube. A burst of current through the tube causes an emission of X-rays limited in duration to a millionth of a second. Bullets can be photographed with this apparatus as they pass along the gun barrel.

So far we have been concerned for the most part with the taking of a single photograph: with snatching a fleeting instant from the passage of time to reveal one phase of an event, and with methods whereby we can ensure that we capture the instant of interest. If we wish to study the whole course of an event, we must turn to the cinematograph. In the high-speed cine-camera the pictures are taken at a much greater rate than that used for projection, and so the event is stretched out in time.

In projection at least sixteen pictures must fall on the screen in each second if flicker is to be avoided and the appearance of continuous motion is to be obtained. The modern high-speed cine-camera will take 3,000 pictures per sec. We are thus able to slow down the motion in the ratio of 3,000 to 16, a factor of about two hundred times. For this reason the high-speed cine-camera is often referred to as a 'time microscope', which, in the case I have quoted, can be said to have a 'magnification' of two hundred times.

In the ordinary cine-camera the film is moved intermittently. This is impossible at high speeds; the film must run continuously and the desired result must be produced in other ways. Edgerton overcomes the difficulty by using his discharge lamp to illuminate the subject by a succession of flashes to give the separate pictures on the continuously running film. The value of the method to modern industry will be obvious.

In industrial applications, however, it is rare that one can bring the problem to the laboratory. We need readily portable equipment, such as the Kodak High Speed camera. The subject is illuminated in the ordinary way, that is, continuously. The film also runs continuously through the focal plane of the lens. Between the lens and the film a block of glass rotates to form a shutter and to provide optical compensation for the film movement (Fig. 3). The glass block is fitted with vanes which form part of the surface of a cylinder and act as shutters. During each revolution, light from the lens is admitted to the film and a photograph is taken. The light is refracted downwards by the glass block as it passes through the vertical position in such a way that the image moves with the film and relative motion is avoided.

At a frequency of 3,000 pictures per second—the maximum speed of the camera—the time of exposure of each photograph is 1/10,000 sec. At this frequency the film is travelling at 75 ft./sec., and, were it not for the optical compensation, the exposure time would have to be reduced to a few millionths of a second to reduce the effects of film movement to negligible proportions. These conditions can be met by Edgerton's flashing lamp technique, but only with sacrifice of illumination. For the analysis of many phenomena, the most important requirement is a high frequency of picture taking: given this, the exposures of the separate pictures can be relatively long, and the ability to expose for so long as 1/10,000 sec., conferred by optical compensation of film movement, greatly simplifies illumination problems which, however, remain formidable enough. Illumination of the subject to a level approximating to sunlight on a fine summer day is necessary.

The camera is comparatively light and compact. It takes a 100-ft. roll of film of the type normally used for amateur cinematography. The base of the camera has been fitted with a timing device. This consists of an electrically controlled 1,000-cycle tuning fork, a small lamp and an optical system which throws an image of the lamp filament on to the edge of the film. The light beam is interrupted by shutter blades attached to the prongs of the fork to give a series of dots along the edge of the film at 1/1,000 sec. intervals.

In the ideal case the photography is simple. However, each problem usually presents special difficulties which must be overcome. A typical example is afforded by an investigation which was carried out of the performance of a drop forging hammer. The hammer weighed 8 tons and the whole machine was based on some 500 tons of concrete. The users were concerned by the slight displacements which took place in this massive base. It was desired to know the extent of movement of the anvil under impact. Observers had put the figure at between ¼ in. and 2 in., and we were asked to carry out measurements

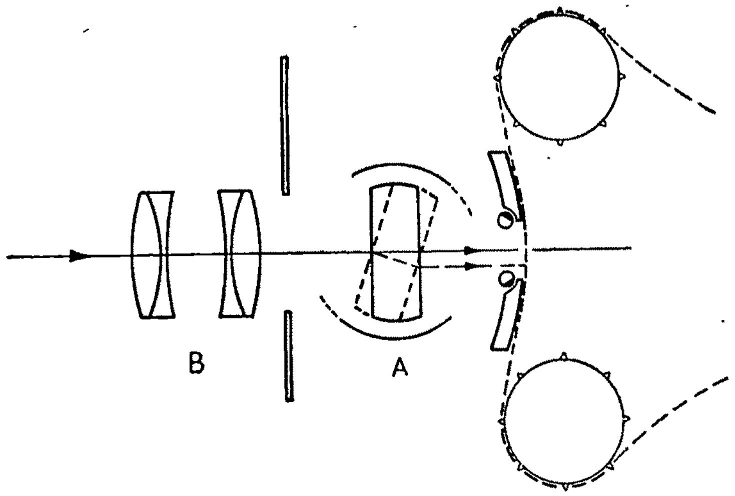

Fig. 3. SCHEMATIC DIAGRAM OF A NON-INTERMITTENT CINE-CAMERA WITH OPTICAL COMPENSATION.

by high-speed photography. The problem would have been simple but for two facts. First, on impact there was a cloud of smoke and flame from the fluxes used in the mould, and the anvil was largely obliterated. Secondly, everything in the vicinity rocked as if by an earthquake, and there was no possibility of insulating the camera from the violent vibrations. Thus it was necessary to include in each photograph some fixed object to which the displacement of the anvil could be referred. This was found in a low-frequency pendulum suspended at the centre of a stretched elastic cord. Vanes attached to the bob of the pendulum dipped in an oil bath and prevented any other than vertical motion. The low frequency of the pendulum—of the order of 2 sec.—prevented it from moving until long after the impact. Thus movements of the anvil only were recorded. A vane on top of the pendulum partly obliterated the image of a bright light source reflected into the camera from a prism which was fixed in the anvil. When the anvil moved, the slit image of the light source widened and narrowed, and these movements were photographed. An analysis of the photographs showed that the movement ended in 1/200 sec. and the maximum displacement was 1/20 in.—five times less than the lowest visual estimate.

Sometimes it is the analysis of the records, and not the photography, which presents unusual difficulties. An ingenious method to overcome them is due to the L.M.S. Railway Research Laboratory. In an investigation of the influence of the profile of the carriage wheel on the smoothness of running of a train, it was desired to measure the sideways motion of the wheel on the rail during travel. Arrangements were made to take a cine-picture of the point of contact of rail and wheel. On each of the many thousands of photographs obtained, the displacement had to be measured—an almost impossible task by ordinary means. The special apparatus which was devised allowed the measurements to be made easily and quickly. In place of the usual cine-projection screen, a 'recording screen' was used, and during projection of the film the recording paper was moved synchronously with the passage of the film through the projector. One observer by means of a lever was able to move the whole screen bodily sideways to keep the image of the rail against a datum line. Another observer kept an index on the image of the wheel and made a trace on the paper. The distance of this from the datum line gave the required information—a kind of 'indicator diagram' on the recording screen which could be evaluated mathematically.

These two examples of the way in which physical devices are used to overcome experimental difficulties must suffice. I am very conscious of many omissions. I have not mentioned Sir Charles Boys' ingenious lightning camera which, in the hands of Schonland and others, has been so fruitful in the analysis of the lightning discharge. I have not mentioned the large amount of work on flame propagation which has resulted in the unravelling of many of the mysteries of combustion[1] by Ellis, Bone and Frazer, to mention three outstanding workers in Great Britain.

My excuse must be that the possibilities of wedding experimental ingenuity to photography are almost boundless. Another omission is the analysis of very slow phenomena. Perhaps here I may plead that there is no problem. There is no difficulty in taking photographs with intervals of minutes or days. The film is projected at normal speed and the passage of time is telescoped. In this way much light has been shed upon such phenomena as cloud formation, the growth of plants, the opening of blossoms, etc.

AREA AND NUMBER OF SPECIES

By DR. C. B. WILLIAMS
Rothamsted Experimental Station

FOR many years there have been discussions of the relation between the size of a sample of an animal or plant community and the number of species contained in it. Until recently, however, most of the approach has been from the botanical side.

So long ago as 1859 Watson[1] gave a table of the area and number of species of flowering plants in each of the 18 provinces and 38 sub-provinces into which he divided Great Britain, and commented on the fact that one square mile of diversified country in the north of Surrey contained nearly half the species of plants of the whole 760 square miles of the county. Much later, Willis[2] touched on the same problem from a slightly different angle, as he was more interested in the frequency of species with different distributions than with the actual number of species in one area. The question was then taken up by Arrhenius, Gleason and others by the use of the quadrat system of examining very carefully all the plants on a number of quite small areas as a random sample of the whole.

Arrhenius[3] considered that the relation between area (A) and number of species of plants (S) on various sizes of plots in the same botanical association was given by the formula A varies as $(S)^n$ where n is a constant for the population under consideration. Rich types (that is, associations rich in species) have a low n value and poor types a high value, but the range of n was quite small. This relation should give a straight line when the log of the area is plotted against the log of the number of species. On the whole the fit of Arrhenius's calculated figures to the observed numbers was not good, and in some examples, especially for rather large areas, very poor indeed.

Gleason[4] studied data from a number of plots of different sizes in an aspen association in Michigan. He came to the conclusion that a straight-line relationship was obtained when the log area was plotted against the actual number of species, and not its logarithm: otherwise that A varies as n^S. This gave a distinctly better fit than Arrhenius's figures for larger areas, but when extrapolated towards the smaller areas gives the curious result that certain small areas must have no species—or even less than none!

Both these theories were developed empirically to find a graph to fit certain observed results, and they were not based on mathematical reasoning.

In all the work on plants, the areas have been the basis of comparison between two or more samples. Plants are sedentary, so that it is easy to decide which plants belong to any particular area; and within one ecological association the number of individuals is probably proportional to the area. On the other hand, it is difficult in many species of plants to decide where an 'individual' begins and ends. In animals the reverse is the case; it is nearly always possible to recognize the individual; but, owing to their mobility, it is difficult to say which animals belonged to which area, particularly if this is small.

The problem of the relation between the number of individuals and the number of species in a random sample of a mixed animal population has been recently taken up. R. A. Fisher has developed a mathematical theory of sampling, based on certain assumptions as to the frequency distribution of different species in the population sampled; and I have shown that these conclusions are very closely supported by results obtained in the field by random samples of insects in a light-trap[5].

Fisher's work suggests that the relation between the number of species (S) and the number of individuals (N) in random samples of a mixed population is given by

$$S = \alpha \log_e \left(1 + \frac{N}{\alpha}\right).$$

The value α is a constant for the population and we have called it the Index of Diversity. It is large for populations rich in species and small for those with few species, and it has a very considerable range of values in observed samples.

If for any one sample from a mixed population we know the number of individuals and the number of species, then α can be calculated, and hence we can find how many species would be represented in any other sized sample from that population. Fig. 1 shows the observed numbers of species of Lepidoptera in samples of eight different sizes taken by means of a light-trap at Harpenden during the years 1933–36. The same diagram shows the calculated relations for various values of α, and it will be seen how closely the observed figures are to the calculated values for $\alpha = 40$. Even the slight departure from this theoretical curve can be explained by the fact that sampling covered several years.

It will be noted that, in Fisher's formula, if the size of the sample N is large compared with α, then the 1 can be neglected in relation to $\frac{N}{\alpha}$ and S is proportional to $\log_e N - \log_e \alpha$. Otherwise (since $\log_e \alpha$ is a constant for the population) for large samples there is a straight-line relation between the number of species and the log size of the sample, just as suggested empirically by Gleason for plants. For smaller-sized samples, Fisher's formula departs from the straight line and is a much closer fit to the observed facts (see Fig. 1). Some botanical applications of this theory are discussed in a paper at present in the press[6].

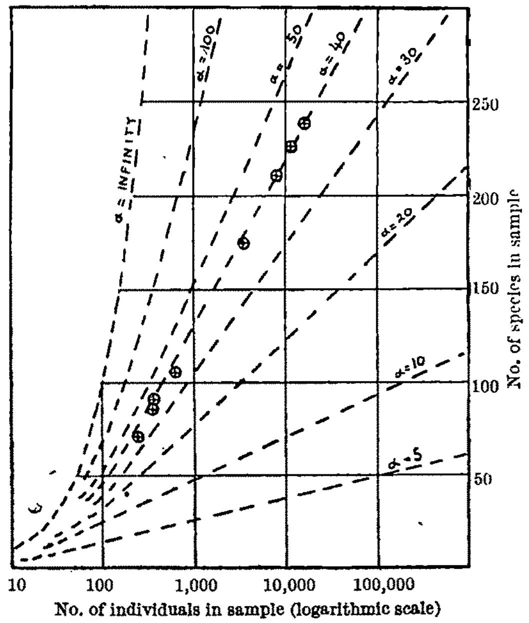

Fig. 1. THE RELATION BETWEEN THE NUMBER OF INDIVIDUALS AND THE NUMBER OF SPECIES IN SAMPLES OF DIFFERENT SIZES, ACCORDING TO FISHER'S LOGARITHMIC SERIES, FOR DIFFERENT VALUES OF THE INDEX OF DIVERSITY 'α'. ALSO THE OBSERVED VALUES FOR 8 SAMPLES OF DIFFERENT SIZES FOR LEPIDOPTERA CAPTURED IN A LIGHT TRAP AT ROTHAMSTED.

This formula gives an apparently sound basis for calculating the relation between the number of species and the size of the sample (either as numbers of individuals or as area) provided that the samples are taken from the same population in the same ecological association. If, in the course of increasing the size of the sample, we extend into a different population or ecological area the number of species will increase more rapidly.

It occurred to me that it would be interesting to see what changes in the number of species were in fact found when the size of the sample was increased far beyond the limits of single ecologically uniform populations. As the number of species concerned is likely to be very large, it was necessary to use for the purpose a diagram showing both species and size of samples on a logarithmic scale, although this does not give a straight-line relationship for sampling from the same population. As plant data appeared to lend themselves better for this study, and to be available in greater quantity, it was decided to plot the number of species of flowering plants against the area sampled over the greatest possible range of areas, from very small to very large.

The results of this investigation are shown in Fig. 2. The heavy central vertical line of the diagram represents one square kilometre of land: to the left

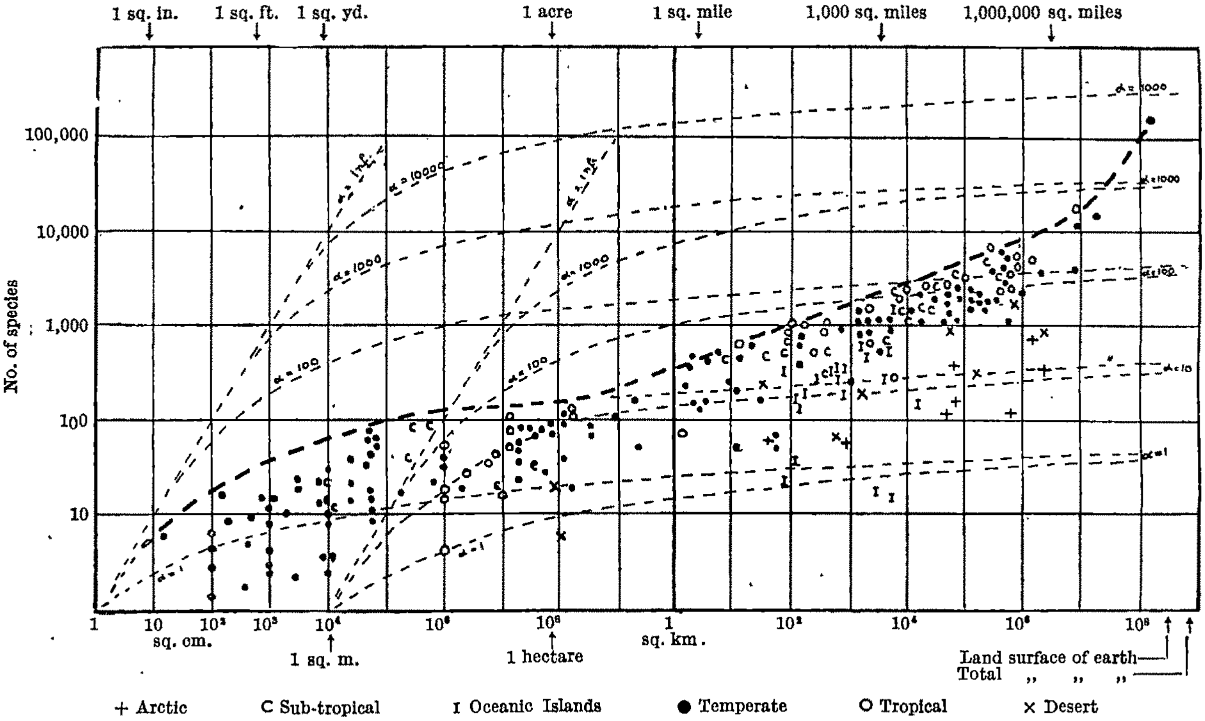

Fig. 2. DIAGRAM SHOWING THE RELATION BETWEEN THE AREA OF A LOCALITY AND THE RECORDED NUMBER OF SPECIES OF FLOWERING PLANTS FOR THAT AREA.

from this the vertical lines represent 1/10, 1/100, etc., of a square kilometre until we reach 1 square centimetre on the extreme left. Moving to the right, we have vertical lines representing 10, 100, 1,000, etc., square kilometres until the one at the right overpasses the total area of the earth's surface. The horizontal lines represent 1, 10, 100, etc., species found in the areas under discussion.

Each point on the diagram represents an actual area of land from which the number of species of flowering plants has been recorded. It was not possible to reproduce here a diagram sufficiently large for each point to be identified to its exact location, so instead they have been distinguished into the chief climatic regions with separate indications of oceanic islands and deserts. The points are not quite evenly distributed throughout the range of the diagram: there is a particular lack of records of areas between two acres and a square mile; and I have only been able to find estimates of the total flora for two continents, North America and Europe. There is a lack of records for small areas both from the tropics and in the arctic and subarctic climates. Many records could not be used because the exact limits of the area were not well defined. In general there is probably a tendency to underestimate the number of species; but, except in a few areas that have been very little studied, the number likely to be added will make very little difference to the position of the record on the logarithmic scale. An increase of 10 per cent in the number of species will only move the point upward through approximately its own diameter.

Superimposed on the diagram by dotted lines are the lines of increase of number of species with size of sample expected by Fisher's theory of randomized sampling in a uniform population (*loc. cit.*). This theory depends on the number of individuals in the sample, and while in general the number of individual plants is proportional to the area sampled, this is not true when we compare grassland with woodland, or woodland with desert or arctic conditions. Available information indicates that there is about 1 plant per square cm. in temperate grassland, about 1 per square metre in woodland, and 1 per 100 square metres upwards in semi-desert areas. The relations on Fisher's series are shown for several different values of the Index of Diversity 'α', and starting from the base line of 1 plant per sq. cm. and 1 per square metre. It will be seen that the lines for the same α values from these two bases gradually approach as the area increases, and for very large areas the number of species to be expected is not very different whether the plant population is dense or sparse. In the extreme case with α = 1 there would only be about thirty-four species in the whole world with 1 plant per square metre, and about forty-two with 1 plant per sq. cm. if the whole world were a uniform eclogical association.

Returning to the distribution of the points on the diagram, it will be seen that they are chiefly scattered over a narrow belt across the figure, the upper limit of which can be divided roughly into three parts. First a period of rapid rise steadily falling away, from the smallest areas of a few square inches to about one or two acres, or one hectare. Secondly, a range of steady rise, almost linear, lasting from about one hectare to large continental areas of about five million square miles. Finally, a very rapid rise from the continental areas to that of the whole land surface of the globe.

It seems to me that these three portions of the limiting curve can be explained as follows. The first part, as will be seen from the diagram, very closely follows the curve for α = 10 of Fisher's theory with about 1 plant per sq. cm.. Otherwise this portion follows the expected increase in species due to increase of size of sample within a uniform population, or within a single ecological association. In other words, up to areas of the order of one or two acres, neither the climate nor the rest of the environment changes very rapidly on an average. As soon as we pass beyond this limit we begin to include new ecological conditions in our sample, with the result that the number of species will increase more rapidly than would be expected if the population sampled remained uniform. This is the second portion of the curve, and the increase of species continues steadily as we increase the size of samples, gradually including more and more variety of ecological formation due either to climate, soil, slope or other differentiating cause. This process continues until we reach the approximate limits of the continents. The slope of this linear portion of the boundary is such that an increase of 1 in the log number of species corresponds to an increase of about 5 in the log area. Otherwise it appears, empirically, that over this range the optimum number of species increases approximately as the fifth power of the area; to double the number of species the area must be increased by thirty-two times.

When we add continents together to get the flora of the whole world, an entirely new factor comes in, that of the evolutionary origin of the floras. Fewer species are common to two continents than to two halves of the same continent. The floras have evolved differently. Therefore, on adding two continental areas together we get a sudden increase on the number of species, far beyond that due to the increase of ecological variety within the area. This is the last steep portion of the curve.

Thus the inverted S-shaped form of the boundary of the belt of points appears to be consistent with the known facts of sampling technique, ecology and evolution.

The position of the points within the belt can be used for pointing out resemblances and differences which may be of great interest. It will be seen, as might be expected, that the tropical and subtropical areas have in general rather more species on the same areas, but the temperate areas run them very closely. On the other hand, the lower portion of the belt is largely made up of floras of either arctic areas, deserts or oceanic islands. The two isolated 'I's' between 10^3 and 10^4 square kilometres are Kerguelen Island and South Georgia, both oceanic islands with, in addition, a sub-arctic climate. If a much larger number of points could be obtained it would be of interest to tabulate each type of climate separately—and possibly to distinguish some of the different associations, such as forest and steppe, which cover large areas.

It is possible from this type of diagram to make rapid comparisons between areas of similar size with different numbers of species, and between areas with the same number of species but different sizes; and new areas can be placed on the diagram and rapidly assessed in relation to those already known.

This enables one to take in a comprehensive view of a range of phenomena which has been insufficiently studied; and also makes it possible to make rapid comparison between the richness of flora of different areas, at the same time allowing for the differences in size. Up to the present it has been easy to compare floras of similar areas but very difficult if they were dissimilar.

I should be glad of any data of area and number of species for other localities so that the diagram can be made more complete and later republished on a much larger scale.

CHROMOSOMIN, A PROTEIN CONSTITUENT OF CHROMOSOMES

By Dr. E. STEDMAN, F.R.S., and Mrs. ELLEN STEDMAN

University of Edinburgh

According to current views, the nuclei of the cells of animals and plants consist, apart from water and lipoids, essentially of two substances: a basic protein (protamine or histone) and nucleic acid. These two constituents are supposed to form a salt-like compound, known as a nucleoprotein (protamine or histone nucleate), which constitutes the so-called chromatin of the nucleus. The results upon which these views are based have been largely derived from chemical studies of the heads of fish spermatozoa. Thus Miescher[1], the pioneer worker on this subject, calculated that the dried heads of salmon spermatozoa contained as much as 96 per cent of salmine (protamine) nucleate, while H. Steudel and Peiser[2] claimed to have reconstituted the nucleoprotein of herring sperm (that is, the dried heads) by the simple expedient of mixing solutions of equivalent quantities of clupein sulphate and deoxyribose-nucleic acid, the protamine having been prepared from herring sperm itself and the nucleic acid from the thymus gland. Other data of a confirmatory nature have been published by various authors, and the results so obtained from the investigation of fish sperm have been generalized and applied to all nuclei, largely on the basis of their histological similarity.

According to a recent review of the subject in NATURE[3] which should be consulted for further references to the literature, this conception of the composition of the nucleus still holds for ripe sperm and for nuclei with chromosomes in metaphase, although in the resting nucleus the euchromatin is believed, on the basis of the ultra-violet absorption spectra determined with the quartz microscope by Caspersson, to contain a small amount of a protein of the globulin type. Some doubt has, however, been raised[4] as to the possibility of distinguishing proteins in nuclei by this method.

These opinions regarding the chemical composition of the nucleus are, however, incorrect.

In the course of investigations which have extended over several years, we have succeeded in isolating from nuclei, in particular from fish sperm, not only a histone (or protamine) and deoxyribosenucleic acid, but also a protein of a new type which we have no hesitation in saying represents quantitatively the major constituent of the nucleus. As will be shown below this protein constitutes the chromatin of the nucleus and hence forms the principal component of the chromosomes. On this account we suggest for it the name of chromosomin. According to geneticists, the chromosomes are the transmitters of hereditary characters. If this is the case, it is evident that chromosomin must play a major part in such transmissions.

Chromosomin is present in all the animal nuclei which we have so far examined. We have not yet determined whether its composition varies with the species from which it is isolated; such variation is, however, to be expected. Nevertheless a protein with the same general properties has been isolated from both cod and herring sperm, from the nuclear material obtained from ox spleen and from the nuclei present in the Walker rat carcinoma.

The most detailed examination of it which we have so far been able to carry out has been made with the chromosomin from cod sperm, and the following data refer in particular to this substance. As isolated from the nuclei it possesses predominantly acidic properties. It is soluble in alkalis and can be precipitated from the solutions so formed by the addition of acids. When free from salts it is dissolved to some extent by dilute acetic acid, but the solution tends to set to a gel. Owing to its insolubility in acetate buffers (about pH 3·0–5·0) we have not yet been able to ascertain its exact iso-electric point, but this evidently lies somewhere between these pH values. About 25 per cent of the molecule is composed of basic amino-acids, there being present arginine (9·5 per cent), histidine (5 per cent) and lysine (11 per cent). The value for arginine is, we believe, quite accurate; those for histidine and lysine may require slight adjustment in the future, but such adjustment, if necessary, will only involve a change in the relative amounts of the two amino-acids. The acidic properties which chromosomin possesses, despite its high content of basic amino-acids, are almost certainly due to the presence in the molecule of relatively large amounts of glutamic acid, which substance we have isolated in a pure crystalline state from its hydrolysis product. Aspartic acid has similarly been isolated, although in smaller amount. Chromosomin is also characterized by its relatively large content of tryptophane. Other mono-amino-acids, including cystine (0·4 per cent), are also present, but their identity has not yet been ascertained. A small amount of labile sulphur is lost from the nuclear material during the isolation of chromosomin; the origin of this is, however, undetermined.

That chromosomin represents the principal component of the chromosomes is readily shown by staining experiments. For this purpose we have used a preparation dried by successive treatment with alcohol and ether and so rendered completely insoluble in water. When such material, which corresponds to the fixed tissue of the histologist, is placed in a solution of a basic dye (for example, methylene blue, gentian violet) it takes up the latter by virtue of its acidic properties, and on repeatedly washing the centrifuged material with water, the dye is slowly removed. In this respect the behaviour of chromosomin parallels that of the chromatin in the nucleus. Other acidic proteins would, no doubt, behave similarly; chromosomin is, however, the only protein of this type present in any considerable amount in the nucleus.

But perhaps the most convincing evidence of the identity of chromosomin and chromatin is its characteristic behaviour towards hæmotoxylin. When stained with this dye it assumes the typical blue colour familiar to histologists. The stain is, moreover, very firmly held despite repeated washings with water. Casein, an acidic protein not found in the nucleus, is also stained by hæmotoxylin, but in this case the material assumes a purple colour which is quite distinct from the characteristic blue produced with chromosomin. There can, we think, thus be no doubt that the staining properties of chromosomes are due to the chromosomin in these nuclear organs.

It is, we believe, generally assumed that nucleic acid, the only acidic component of the nucleus hitherto known, is mainly, if not entirely, responsible for its behaviour towards basic dyes, and on this postulate the hypothesis has been developed that the chromosomes are largely composed of this acid. This hypothesis receives apparent confirmation from the results obtained with Feulgen's stain. It is, in fact, now generally believed that Feulgen's reagent which, according to its discoverer, reacts specifically with the hydrolysis product of deoxyribosenucleic acid, is capable not only of detecting nucleic acid in the nucleus but also of locating its actual position. While there is little doubt that Feulgen's reagent is of great service in detecting deoxyribosenucleic acid, the idea that it can locate the position of this material in the nucleus is based on a misconception of the processes involved. The stain, whatever its exact nature may be, liberated from the reduced magenta by the hydrolysed nucleic acid, is freely soluble in water. Hence, once it has been formed in the nucleus, it is capable of behaving exactly as do other basic dyes. Apart from the necessity of hydrolysing the nucleic acid before the application of the stain, Feulgen's technique differs from ordinary staining technique merely in the fact that the stain is developed inside the nucleus in limited amount and is not applied from outside. That this explanation is correct can be readily demonstrated. If some hydrolysed deoxyribosenucleic acid is treated with Feulgen's reagent and the mixture allowed to stand until the colour is fully developed, a clear solution with a purple colour is obtained. If some chromosomin is now introduced into this solution, it takes up the dye in exactly the same way as do the chromosomes, assuming a purple colour with a much bluer tinge than that of magenta itself.

The staining properties of the chromosomes towards both basic dyes and Feulgen's reagent are thus due to their content of chromosomin, and the evidence indicating the presence in them of nucleic acid is shown to be fallacious. Nevertheless, we do not wish to claim that the chromosomes are composed entirely of chromosomin. Other undetected substances may be present in small amount, and the facts we have adduced do not exclude the presence of some nucleic acid. A consideration of some quantitative data, however, points to the conclusion that at least part of the nucleic acid is exterior to the chromosomes. Thus, of the three main components of dried nuclei, namely, chromosomin, nucleic acid, and histone, the last two can be estimated with a fair degree of accuracy, the histone by direct isolation and the nucleic acid by a determination of the phosphorus content. Making the assumption, which we believe to be substantially correct, that the remainder of the material consists of chromosomin, we arrive at the composition of the nuclei.

The following results were obtained in this way:

Nuclei	Nucleic acid	Histone	Chromosomin
Cod sperm	28%	12%	60%
Ox spleen	34%	16%	50%
Walker rat carcinoma	26%	1·6%	72·6%

It should be emphasized, however, that the composition of the nuclei is not constant. Some specimens of cod sperm which we have examined have, for example, contained as much as 23 per cent of histone, while the nuclei from the rat carcinoma have sometimes failed to yield any histone at all. The figures do, however, indicate that chromosomin forms the largest constituent of the nucleus, and since it represents the characteristic substance of the chromosomes, there would appear to be little material left to form the nuclear sap unless this contained some nucleic acid. It is an attractive hypothesis, but one for which there is no direct experimental proof, that the spindle which is formed at metaphase is a gel of nucleic acid. The attachment of the chromosomes to the equatorial plate of the spindle could then be conceived as involving perhaps the acidic groups of the nucleic acid and basic groups of the chromosomin, the acidic groups of the latter being neutralized by the histone. Alternative methods of combination are, of course, possible. But the important experimental fact is that the nucleus is composed of at least three amphoteric substances: chromosomin, nucleic acid and histone (or, in special cases, protamine), two of these possessing predominantly acidic properties and one, the histone, predominantly basic properties. Between three such substances a number of salt-like unions could be formed, the nature of which would be controlled by the acidity of the medium in which they existed. It is not, however, our present purpose to speculate on the nature of the changes which occur in the nucleus; discussion of this and other aspects of our work will be reserved until it is possible to give a more detailed account of our experiments.

We desire to thank Dr. A. Haddow of the Chester Beatty Cancer Research Institute for providing us with the Walker carcinoma tissue, and the Medical Research Council for a grant to one of us.

OBITUARIES

Sir Stopford Lauder Brunton, Bt.

SIR STOPFORD BRUNTON, who died on July 25, was the elder son of the late Sir Thomas Lauder Brunton, the eminent physician. He was born on October 11, 1884. He was educated at Cheltenham College, from which he went to the Royal Military Academy, Woolwich, and later to McGill University, Montreal. There, after studying mining geology, he took his degree in 1912. He worked on the Canadian Geological Survey until the War broke out in 1914. Holding a commission in the O.T.C., he drew up a scheme of military training which was accepted at Ottawa, and led to his being sent to France to study modern methods of field-defence. On his return to Canada he raised No. 6 (McGill) Heavy Siege Battery, recruited from graduates and undergraduates of the University, and as officer commanding, took his unit to France in 1917, remaining on that front until the end of the War.

For the next six years Sir Stopford was engaged on survey and mining in Nova Scotia. The results of his work were embodied in two publications, the second of which, "The Gold Deposits of Nova Scotia: a New Hypothesis concerning the Structural Features of the Province", published in 1925, was awarded the Leonard Gold Medal for 1927, jointly by the Engineering Institute of Canada and the Canadian Institute of Mining and Metallurgy. Sir Stopford, in spite of failing health in recent years, was keenly interested in agricultural progress in Nova Scotia, where he owned a farm.

Inheriting the high ideals of his father and something of the fine quality of his genius, he had much personal charm and a kindly, unselfish, generous nature, to which the affectionate devotion of his friends and former comrades offers a fitting tribute. Sir Stopford married in 1915 Elizabeth, daughter of Prof. J. Bonsall Porter of Montreal, and leaves a son and a daughter. The former is now serving in the Royal Canadian Army Medical Corps.

Dr. A. C. Klebs

DR. ARNOLD KLEBS, the eminent Swiss medical historian, died on March 6 at Nyon, on the Lake of Geneva. Born on March 17, 1870, the son of Prof. Edwin Klebs, the famous bacteriologist who was successively professor of pathology at Bern, Würzburg, Prague, Zurich and Chicago, he received his medical training at Bern, Kiel, Würzburg and Berlin, and qualified at Basle in 1894. After post-graduate work in London and Paris, he went to the United States at the age of twenty-six. He gained a reputation by his work on tuberculosis, for which he founded a sanatorium in Alabama and a tuberculosis institute in Chicago. Afterwards he made the acquaintance of the late Sir William Osler, who inspired him with an interest in the history of medicine.

One of Klebs' earliest articles on this subject was the history of inoculation against smallpox (1913). Eventually he published a large number of medico-historical essays either independently or in collaboration with Sudhoff, to whom he devoted a remarkable article on Gianmatteo's "Practica" in the *Festschrift* in honour of Sudhoff's seventieth birthday.

In 1921 Klebs played an active part in the foundation of the Swiss Society of the History of Swiss Medicine and Sciences, which holds a congress regularly every year. In 1938 he published a standard work, "A Short Title List of the *Incunabala scientifica medica*". His last great work was a bibliography of the writings of his friend Harvey Cushing, which appeared on the occasion of the seventieth birthday of the great brain surgeon. His own seventieth birthday was celebrated by Prof. Henry Sigerist, of Baltimore, in a *Festschrift* which appeared in the *Bulletin of the History of Medicine* in 1940. His last years were embittered by the War, which deprived him of the visits of his friends in Europe.

J. D. ROLLESTON.

WE regret to announce the following deaths:

Prof. F. Bacon, professor of engineering in University College, Swansea, on August 23, aged sixty-two.

Prof. W. G. de Burgh, F.B.A., emeritus professor of philosophy in the University of Reading, on August 27, aged seventy-six.

Prof. John Hilton, professor of industrial relations in the University of Cambridge, on August 28, aged sixty-two.

NEWS AND VIEWS

The British Council

The report of the British Council for the year ending March 31, 1943 (London: British Council, pp. 108), indicates a steady expansion of the work of the Council making known the life and thought of Britain abroad. The detailed description of the exchange between this and other countries of information on the work of men of science, doctors, engineers, teachers, lawyers, trade unionists, scholars, musicians and artists given in the report indicates the way in which the Council is helping to bring about a real place of understanding by the people of the peoples of the world and the increasingly important place of the Council's work in the United Kingdom in relation to the future of Europe. The Council is responsible for the educational and cultural welfare of the Armed Forces of our European Allies stationed here, for that of Allied neutral merchant seamen reaching our ports, and for that of foreign civilians, and the facilities for instruction and recreation made available have proved no less welcome to the Armed Forces of the Dominions, in particular the Canadian Army and Royal Canadian Air Force and soldiers, seamen, technicians and others from the British Colonies and India. The Conference of Allied Ministers of Education which was initiated at the suggestion of the Council has appointed two Commissions—one to consider the negotiation of bilateral treaties of understanding or cultural conventions and the other to report and make recommendations on questions affecting the supply of books and periodicals to the occupied countries of Europe after the War, including the restocking of national and university libraries destroyed or damaged by the Germans, the provision of text-books for university students and for schools, and a brief factual history of the War. In Turkey a number of university appointments were made by the Turkish authorities on the Council's recommendation, including that of Dr. F. A. Constable to the chair of physical chemistry at the University of Istanbul. An exhibition of photographs of British scientific achievements was opened at Istanbul, and in the Soviet Union the recently established scientific bureau of the U.S.S.R. Society for Cultural Relations has appointed the head of the Council's Science Department as its agent for the supply of information about science and scientific workers in Britain. A number of articles have been written especially for the Scientific Bureau by Sir Stafford Cripps, Dr. Julian Huxley, Dr. C. D. Darlington and Mr. J. G. Crowther.

With regard to science, in addition to continuing the issue of *Monthly Science News*, a series of broadcast talks have been arranged or advised for the B.B.C. Overseas Service and a number of volumes published in the "Science in Britain" series. Arrangements were made for the medical abstracts prepared by the British Medical Information Service to be printed under the title of *British Medical Bulletin*, and these abstracts are sent to the editors of overseas medical journals in English, Spanish and Portuguese. A number of original articles, commissioned from British medical experts, have been published or accepted for publication in medical journals of good standing. Considerable attention has been given to medical films. The Medical Department of the Council is answering an increasing volume of general medical inquiries from other countries. The Engineering Panel has advised on questions affecting technical education in Turkey and articles on engineering science have been forwarded to Turkey, Egypt, the British West Indies and elsewhere. Many foreign universities and educational authorities rely on the Council to recommend British scholars or research workers to fill University appointments abroad, and the Council has also participated in the training of Allied personnel for reconstruction, a number of scholarships having been awarded in collaboration with the Allied Governments for post-graduate and undergraduate study, and a further course has been arranged in London for Allied civil servants, with lectures on British administration and classes on British diplomatic and legal terminology.

The Council has continued its policy of presenting books to increase the libraries of British institutes and anglophile societies, in universities, schools, libraries and other institutions abroad, and in the United Kingdom to British subjects from the Empire and foreign lands, a very substantial proportion of the books sent abroad being of a scientific, technical and specialized kind. The Council has continued to take a direct interest in the export trade of books both by encouraging the sale of British books of cultural value in foreign bookshops, conducting its exhibition of books which have a commercial as well as a prestige value, facilitating the review of British books in the foreign press and arranging for the publication of more British books in the original or in translation.

Review of the Aircraft Industry

The tenth report of the 1942–3 session of the Select Committee on National Expenditure pays brief tribute to the remarkable industrial achievement of the aircraft industry. The production of aircraft is now substantially balanced, and, with the exception of spares, there is at present no single field of production where a serious bottleneck threatens to retard output. Most of the Committee's recommendations are minor, but taken together they suggest that there is still room for considerable all-round improvement in the efficiency of the industry. Better personnel management, for example, should assist in reducing an excessive turnover of labour. Again, the industry is suffering from an acute shortage of scientific and technical men and there are not enough adequately qualified men to maintain the industry at the proper level of efficiency, this applying also in the whole field of aeronautical research. Special measures are necessary and men of high academic, scientific or technical attainments should not, in the Committee's view, be allowed to be absorbed in the fighting services, where, even when they are employed in technical jobs, their qualifications are often much higher than is needed. Facilities should be provided for training scientific and technical personnel as well as for training managerial staff of all grades, including foremen, and more use made of the Ministry of Labour's courses in foremanship.

In regard to the dissemination of scientific and technical information the Committee considers that bearing in mind the limitations upon publication which the need for secrecy imposes, the arrangements on the strictly scientific side are adequate. Firms who are in difficulties with regard to technical problems can get the fullest possible help from other firms, but for reasons of prestige are sometimes reluctant to apply for help. In the less technical problems firms are not always ready to profit by the experience of others, and the report comments on the aircraft industry's neglect of statistical methods of quality control. Other recommendations for improving efficiency include the strengthening of design staffs by the appointment of draughtsmen with actual experience of production engineering, and arranging that design and development offices and planning departments are within the same premises and housed as close to each other as possible. More appointments similar to that of the technical advisor to the chief executive should be made, even if it involves the temporary withdrawal of men occupying important positions in the industry. In regard to the co-ordination of production with research and development the report notes that the importance of this requirement has lately received greater recognition, and strenuous efforts are made to this end through weekly meetings of the controller of research and development with the officers responsible for production. The advantages of collective consultations on the allocation of orders in important changes of programmes are stressed and also the necessity for close attention to the problem of reducing the loss of output caused by change-over from an old to a new type.

Dr. Carl Voegtlin

DR. CARL VOEGTLIN has resigned from the directorship of the National Cancer Institute, U.S. Public Health Service. Dr. Voegtlin, who has been director of the Institute since its foundation in 1938, is sixty-four years of age. He has recently been presented with a portrait of himself at a meeting of the U.S. National Cancer Advisory Council. Before taking over as director of the National Cancer Institute, Dr. Voegtlin had been chief of the Division of Pharmacology in the National Institute of Health. He went to that Division of the U.S. Public Health Service in 1913 from Johns Hopkins Medical School, where he had been associate professor of pharmacology. Born in Switzerland and educated in the Universities of Basel, Munich, Geneva and Frieberg, Dr. Voegtlin has had a distinguished career, and an international reputation for his researches in physiology, pharmacology and cancer.

Summer School in Biology and Health

APPROXIMATELY 250 students attended the Summer School in Biology and Health of the Central Council for Health Education held during August 4–14 at the Chelsea Polytechnic, London. They represented a very wide variety of educational activity, including junior, senior and secondary school teachers, head teachers, training college lecturers, health visitors and nurses, educational administrators, teachers of physical education and domestic science, and representatives of commercial houses. This mixture of different categories was particularly valuable in discussion, since it enabled the various points of view to be expressed. These discussions, and particularly those on sex education, were most fruitful. During the School, students visited experimental stations, health centres and clinics, and there were demonstrations of biological experiments, health education pamphlets and teaching material. In addition, there was a display of text-books and shows of biological and health education films.

Among the lecturers at the School were Dr. Charles Hill, who gave the inaugural address on "Biology and Health", Prof. C. W. Valentine and Prof. Lancelot Hogben of Birmingham University, who spoke on "Early Childhood" and "Biology as a Social Science" respectively. Miss Enid Blyton described "Education Through Story Telling", Miss F. Brackenbury gave an address on "Practical Methods in Health Teaching", Prof. J. R. Marrack spoke on "Social Aspects of Nutrition", Mr. L. J. F. Brimble lectured on "Social Studies and World Citizenship", and Sir John Russell gave the final address, on "Agricultural Developments in the U.S.S.R." The demand to attend the School was so great that many prospective students had to be turned away, and it is likely that next year more Schools will be held both in the North and in the South of England.

Sociological Value of Family Meals

FAMILY table talk plays a vital part in rearing children. During mealtime, the time when the whole family is likely to be together, children learn moral values, absorb family culture, and develop as individuals, according to Prof. J. H. S. Bossard, of the University of Pennsylvania (*Amer. Sociol. Rev.*, June 1943). The dining-room is often the real social centre of the household, and the family is apt to be at its greatest ease at the dining table. The influence of conversation at this time is subtle and intangible, but the part which it plays in rearing children is most important.

Mary's place in the family group becomes most clearly defined and the family serves as her sounding-board during meal-time. Both in the responses given and withheld, the family carries great weight in the moulding of her personality. It is here that the individual members aid in enlarging each other's vocabulary, and "facility and quickness in expression constitute the price for admittance to the conversation", states Dr. Bossard. The family dining table is likened to a clearing house for information, news, and experiences. In some families, according to Prof. Bossard, meal-time serves as a forum, sometimes it substitutes for class-room instruction, and again it may be the one place where problems of importance to the entire family are thrashed out. A child's interests can be stimulated and directed during meals. If Mary has artistic, literary, or mechanical interests, family table talk can either increase or dampen the development of these interests.

Almanacs and Health Education

ACCORDING to an editorial in the February issue of the *Boletín de la Oficina Sanitaria Panamericana*, almanacs have recently been revived as a means of health education. The Division of Malariology in the Argentine, for example, lately used this device in its anti-malarial campaign, and in Venezuela the Ministry of Public Health and Social Welfare published health calendars in 1940. The calendar reaches every social level, including peasants, schools, industrial groups and every public and private institution. A national calendar may include among other items notes on scientific advances of general interest, radio progress, museums, periodicals, ways of preparing food, vaccination, rules for maternal and infant hygiene, social security legislation and economic data.

Insect Pests of Stored Products

THE British Museum (Natural History) has recently issued a useful illustrated pamphlet (Economic Series No. 15) entitled "Common Insect Pests of Stored Food Products". Every year many inquiries relating to pests of this kind are received by the Museum. Usually the identification of such pests is not a matter of much difficulty, whereas the giving of advice on control measures is often very far from being easy and straightforward. The provision of this kind of advice is not properly the concern of the Museum staff, and, for this reason, the Trustees have welcomed the recent establishment of a Pest Infestation Laboratory by the Department of Scientific and Industrial Research and of an Infestation Branch under the Ministry of Food. The present booklet has been prepared at the request of these two organizations, and it aims at making easy the identification of the insects and arachnids commonly associated with stored products in Great Britain. The authors, Drs. H. E. Hinton and A. Steven Corbet, have avoided the use of any but the most elementary technical terms, so that the layman—apart from the entomologist—should be able to identify most of the pests that he is likely to come across. The pamphlet is obtainable, price 1*s*., through a bookseller.

Protective Finishes for Scientific Apparatus

THE June issue of the *Journal of Scientific Instruments* consists mainly of three papers which constitute a symposium on "Protective Finishes for Scientific Instruments and Apparatus". In a foreword, Mr. A. J. Philpot, director of research of the British Scientific Instrument Research Association, counters criticism of its value by pointing out the useful purpose served by "Any publication in which there is gathered together in a condensed form the available information on the various technical processes relating to a specific subject". In the present case, stronger emphasis would have been justified. Dr. Sutton's paper, for example, surveys dispassionately, and with the authority of unique experience, the relative merits of various protective treatments for different materials, pointing out the causes of corrosion troubles in instrumental work. It would be difficult, if indeed possible, to find the same information elsewhere in the literature. Dr. Bovey's survey of available anodic oxidation processes for aluminium alloys provides, in small compass, the essential information on their applicability and the characteristics of the films they yield. 'Review', 'summarize' and 'survey' are verbs of particular utility to a reviewer of technical literature. Unfortunately, they do not fit Mr. Wornum's paper on protective paints and varnishes. The most apt description is perhaps 'concise treatise', dealing, as it does, with the underlying principles of the processes involved in applying different types of coating as well as the properties and uses of these. Mr. Philpot may rest assured that there is little need to defend this symposium. It will be welcomed by all who use scientific instruments as well as those who make them.

New Seismograph in Mexico

A NUMBER of prominent American men of science, including Dr. Harlow Shapley, Dr. S. Chandrasekhar, Dr. Percy Bridgman and Dr. L. Don Leet, were present at the dedication of the new seismograph at the National Astrophysical Observatory at Tonanzintla in Mexico by invitation of President Avila Camacho and the Governor of Puebla. The occasion was the first National Conference of Physics at Puebla. The seismograph, which was acquired by the State of Puebla, is a Benioff vertical-component instrument obtained through the National Research Council of Washington and the Harvard Seismological Station, and has been thoroughly tested by the Rev. Daniel Linehan, *S.J.*, of Weston College (*Earthquake Notes*, 14, Nos. 3 and 4; June 1943). The instrument is expected to contribute to a large extent to the study of earthquakes in Mexico and the activities of sleeping volcanoes. The observatory where it has been housed is just east of the mountains Popocatepetl and Ixtaccihuatl. The installation appears to be timely, for a new volcano began eruption in the State of Michoacan, Mexico, on February 20, 1943. This is some two hundred miles west from Mexico City at an elevation of about 6,000 ft., near the town of Paricutin, which has had to be evacuated. Earthquakes are relatively frequent in many parts of Mexico, and a stronger one than normal occurred on February 22, 1943, at a point near the Pacific coast roughly 140 miles from the volcano in a direction 30° east of south. The shock was felt strongly in Mexico City. There is no known connexion between the earthquake and the volcano just mentioned.

Announcements

ON the occasion of President Roosevelt's visit to Ottawa on August 25 the Chancellor of the University of London, the Earl of Athlone, on behalf of the Senate, conferred on him the degree of doctor of laws *honoris causa*. H.R.H. Princess Alice, Countess of Athlone, and the Prime Minister of Canada were present on the occasion; and the oration was read by Captain H. C. Best, professor of physiology in the University of Toronto.

MR. A. W. LING, chief agricultural advisory officer, University of Bristol, has been appointed principal of the Seale-Hayne Agricultural College, Newton Abbot.

PROF. R. A. S. MACALISTER has resigned from the chair of Celtic archæology in University College, Dublin. He is succeeded by Prof. S. F. O'Riordan.

MR. P. G. HYSLOP has ceased to be a member of the Coal Commission of the Minister of Fuel and Power on the expiry of his term of office, and Lieut.-Colonel J. A. S. Ritson has been appointed a part-time member of the Commission to fill the vacancy.

THE British Rheologist's Club is holding a meeting at Loughborough College on September 18 at 10 a.m. The subject for discussion will be "Rheology in the Hosiery, Leather, Shoe and Allied Trades". Further information can be obtained from the Secretary, British Rheologist's Club, c/o Institute of Physics, The University, Reading.

A COURSE of three lectures and discussions on "Engineering Economics" will be given by Sir Frank Gill, director of the International Standard Electric Corporation and chairman of the Standard Telephones and Cables, Ltd., at the Institution of Electrical Engineers on Tuesdays at 5.30 p.m. beginning on September 21. These lectures are arranged by the University of London, and further information can be obtained from the Accountant, University of London, Senate House, Bloomsbury, London, W.C.1.

Riboflavin and Vitamin B_1 in Nineteenth Century Buns and Ale

RECENTLY, one of us (H.S.S.) was presented by Mr. H. W. Hedges, of Fairford, Gloucester, with two currant buns; one was baked in 1863 to celebrate the wedding of the Prince of Wales and the other in 1887 for Queen Victoria's jubilee. Both had been kept as souvenirs of the "Cakes and Ales" custom for celebrating national festivities. Except for a granite-like quality, they were in perfect condition, even to the currants, and on analysis gave the following results:

	1863 bun	1887 bun
Moisture	13·0 per cent	13·6 per cent
Protein	11·4 ,, ,,	11·3 ,, ,,
Fat	5·2 ,, ,,	4·4 ,, ,,
Fibre	0·2 ,, ,,	0·4 ,, ,,
Vitamin B_1	0·15 I.U./gm.	0·35 I.U./gm.
Riboflavin	9·3 μ gm./gm.	7·3 μ gm./gm.
*p*H (1 part bun/2 parts water)	4·4	5·0

Microscopical examination showed that both buns were made with yeast or barm. The most interesting feature of the analyses is the high value for riboflavin; the vitamin was determined microbiologically[1].

Two further buns have been examined (made 1888 and 1890) and gave the following figures (expressed on a 13 per cent moisture basis):

	1888	1890
Fibre	0·4 per cent	0·5 per cent
Vitamin B_1	0·05 I.U./gm.	0·10 I.U./gm..
Riboflavin	5·6 μ gm./gm.	4·7 μ gm./gm.

The average vitamin B_1 and riboflavin contents of the four buns are 0·15 I.U./gm. and 6·7 μ gm./gm., respectively. These figures compare with approximately 1 I.U. and 1·5–2·4 μ gm./gm. for present-day buns. The ancient buns were almost certainly made with brewers' yeast, and it is to this constituent that we must look for the explanation of the high riboflavin content. Incidentally, currants give a value of approximately 1 μ gm./gm.

Examination of a number of dried plain and debittered brewers' yeasts (12–13 per cent moisture) has given the following average results:

Vitamin B_1	33 I.U./gm.	(9·5)
Riboflavin	54 μ gm./gm.	(15)

The figures in brackets are the calculated figures for the corresponding wet yeasts (approximately 75 per cent water content).

The recipe from which the buns were made is unknown, but was possibly something similar to the Hannah Glass 1780 recipe which reads:

"Take two pounds of fine flour, a pint of good ale yeast, and three eggs beaten, knead all these together with a little warm milk, a little nutmeg, and a little salt, and lay it before the fire till it rises very light, then knead in a pound of fresh butter, a pound of rough carraway comfits, and bake them in a quick oven, in what shape you please, on floured paper."

This recipe would indicate a fat content of about 20 per cent in the dried bun, so that it must be assumed that the quantity of butter used in the buns under discussion was not so generous.

In attempting to calculate the vitamin B_1 and riboflavin contents of a "Hannah Glass bun", the difficulty is the yeast content of the "pint of good ale yeast"; despite many inquiries, we have been unable to obtain even an approximate figure. If, however, we calculate backwards, taking the riboflavin contents of flour, eggs, milk and butter as 1·5, 5, 1·5 and 0·1 μ gm./gm. respectively, and assuming ½ lb. of butter and ½ pint of milk in the recipe, it would follow that the pint of ale yeast contained something of the order of 8,000 μ gm./gm. of riboflavin.

As shown above, present-day wet brewers' yeast has a riboflavin value of about 15 μ gm./gm. On the other hand, it was thought that yeast grown on all-malt mashes might have a higher value. Accordingly, a sample was grown in the laboratory and gave on analysis vitamin B_1 and riboflavin figures of 9·3 I.U. and 23 μ gm./gm. (75 per cent water content), or slightly higher in riboflavin than the figure obtained for commercial yeasts. To complete the picture, four samples of present-day beer were examined and gave three values of 0·9 and one value of 1·7 μ gm./c.c. We have since been in touch with Prof. R. H. Hopkins and found that he has also obtained similar results with a wider range of beers and stouts (see p. 274). The explanation for the relatively high riboflavin content of beer has still to be worked out, but assuming there is little autolysis or 'release' of riboflavin from the yeast, it could be explained by assuming complete extraction from the malt if the latter has a value of about 8 μ gm./gm., or more than three times that of raw barley[1]. This is not unreasonable in view of the work of Davis, Laufer and Saletan[2], who found this ratio although their value for raw barley was low, namely, 1·02 μgm./gm. Whatever the explanation, it would appear that beer is not an unimportant source of riboflavin. Further, in the days when it was of much higher gravity, it may be assumed that the riboflavin content was correspondingly higher.

Taking 25 μ gm./gm. and 2 μ gm./c.c. as possible values for yeast and ale, it would follow that for a total amount of 8,000 μgm. each pint of ale yeast contained approximately 300 gm. of wet yeast. Such a quantity is, however, unlikely since it is generally assumed that 5–8 lb. of brewers' yeast for 280 lb. of flour (that is, 25 gm. per 2 lb. of flour) is the limit, at least in bread-making, before a bitter taste appears. We have, therefore, so far been unable to explain satisfactorily the riboflavin values found in these ancient buns. It is, however, due either to the high value for the yeast or beer of those days, or to the larger quantity that could be used. It is also of interest to note that the bread made at that time would probably also have a higher riboflavin content than even present National bread (approximately 1·1 μg./gm.), and this fact will be of importance in any historical survey of riboflavin intake.

The average figure of 0·15 I.U./gm. for the vitamin B_1 content of the buns shows that, unlike the riboflavin, there had been considerable destruction of this vitamin in the 50–80 year interval. It is difficult to fix with any accuracy the extraction of the flour used, but the fibre figure suggests an extraction in the region of 80 per cent.

Riboflavin and Vitamin B_1 in War-time Beers

FOR some time past determinations of these vitamins in beers and stouts, obtained by ordinary retail purchase, have been in progress in these laboratories. For riboflavin a microbiological method[1], latterly improved[2], has been employed, whereas aneurin was measured by a fermentation technique[3] using an appropriate strain of bakers' yeast. When sufficient aneurin was present (in the strongest beers), the thiochrome fluorimetric procedure, involving a fundamentally different principle[4], was used as a check.

The riboflavin results have been surprisingly high in the fourteen beers so far tested, the lowest being 0·47 and the highest 1·2 micrograms per c.c. Strong ales are likely to contain more, but none has so far been tested for riboflavin.

As regards aneurin, results of sixteen beers have ranged from 1 to 6 I.U. per 100 c.c., and here three 'strong' ales have been included.

From other observations in progress, it can already be stated that, while much aneurin is lost from bright beer and is removed with the yeast, almost all the riboflavin present in the original malt remains in the beer, and this is a useful amount.

Inactivation of Enzymes by Irradiation

IN consideration of recent communications[1,2] on the chemical action of X-rays on enzymes, and of the renewal of the discussion on the relative role of 'direct hit' and 'indirect action' in enzyme-ray reactions, it seems to us timely to record here certain observations relevant to this question from an investigation in progress on the influence of ultra-violet light on enzymes.

According to Leibowitz *et al.*[3,4,5] the maltose-splitting and the sucrose-splitting activities of taka-diastase must definitely be attributed to two distinct and specifically different agents. Nevertheless, taka-maltase and taka-sucrase show identical inactivation curves when irradiated by ultra-violet light. The inactivation curve of yeast-sucrase, on the other hand, follows a different course. It seems that it is the nature of the accompanying substances (the 'colloid carriers') rather than the enzyme as such that is of decisive importance for the behaviour of the enzyme under irradiation.

It is generally assumed that the susceptibility of enzymes to radiation is increased by dilution. This principle holds in the case of the enzymes named above for dilution with water. It does not hold, however, if the same enzymes are diluted with an inactivated solution of the corresponding enzyme preparation. In other words, when the concentration of the active enzyme molecules is decreased alone, that of the accompanying substances being kept constant, the effect of ultra-violet radiation becomes independent of the concentration of the substrate, that is, the enzyme. Using concentrated solutions of the inactivated material as diluent, dilution actually exerted a protective action on the stability under irradiation of the enzymes. This again tends to confirm the view that accompanying substances are of primary importance in the mechanism of enzyme inactivation by irradiation.

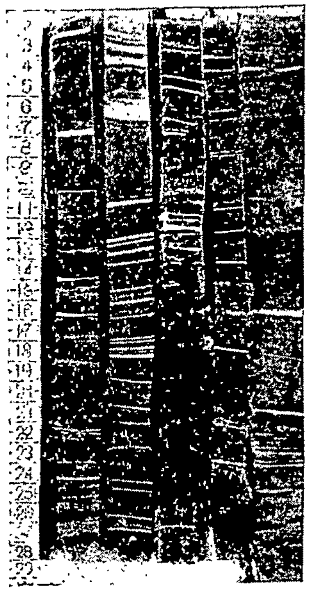
Bacteria in the Bottom Sediments of the Dead Sea

IN order to investigate the presence of different physiological groups of bacteria in the different layers of the bottom sediments of the Dead Sea[1,2,3], it was essential to obtain profiles of mud samples. With a coring instrument designed according to the device of Emery and Dietz[4] a number of profiles 10–170 cm. long, were obtained from depths of 70–330 m. at different places in the Dead Sea during December 1941. It was found that the thickness of the mud layer covering the surface of the bed of the Sea varies in different places from a few centimetres to more than 170 cm. In one place about 6 km. south-west from the northern shore, a profile 170 cm. long was obtained from a depth of 100 m. On dissecting the profile longitudinally, a beautiful 'spectrum of layers', of different colours—black, dark-blue, grey, brown, and white—was revealed (Fig. 1). It is interesting to note that the zones of sedimenta-



'SPECTRUM' OF LAYERS OF A PROFILE 170 CM. LONG OBTAINED FROM THE BOTTOM OF THE DEAD SEA AT A DEPTH OF 100 M.
(*a*) 6–32 cm. (*b*) 32–58 cm. (*c*) 58–85 cm. (*d*) 85–110 cm. (*e*) 110–139 cm.

tion, though distinctly seen, form no seasonal repeat pattern, as, for example, the annual rings of trees.

Thirteen bed samples from six different places were inoculated into enrichment cultures for ten groups of aerobic bacteria and eight groups of anaerobic bacteria. The media was prepared in 25 per cent salt, Dead Sea water (s.g.1·1875) and Dead Sea water (s.g.1·227).

Out of the ten physiological groups of aerobic bacteria growing in 25 per cent salt, thiosulphate-oxidizing and cellulose-decomposing bacteria were found. However, it must be noted that bacterial growth was seen in the enrichment cultures containing kerosine and petroleum as the only source of carbon. In the remaining cultures rich, unspecific growth of bacteria could be seen. In Dead Sea media (s.g.1·1875) thiosulphate-oxidizing bacteria were found and rich growth of unspecific bacteria. The growth in Dead Sea water (s.g.1·227) was slight. Denitrifying bacteria grew in the three different concentrations.

Out of the eight groups of anaerobic bacteria very active lactose- and glucose-fermenting organisms were found at a concentration of 25 per cent salt.

Full details will be published elsewhere.

Sprouting of Potato Tubers

IN an earlier communication[1] reference was made to a U.S.S.R. war-time expedient, namely, accelerated sprouting of potato tubers, which followed the removal of the periderm. This procedure could perhaps be best understood in the elucidation of sprouting itself. The contrasting concepts of changes in oxygen pressure and membrane permeability advanced by some American and Russian workers (private communication from Sir John Russell) register merely the *pulse* of metabolic changes rather than any specific physiological reactions.

Recognizing (1) the accelerator (phyto-hormone, ethylene) as an essential constituent in many phases of plant life[2], and (2) the evolution of the accelerator by the degradation of the inhibitor (blastokolin, maleic acid)[3], I suggest the following scheme as representing accelerated sprouting. The inhibitor ensures dormancy by suppressing enzymic activity (glutathione and consequently glyoxalase and the anaerobic glucose degradation, as well as the activities of succino-dehydrogenase and papain, extending to proteins with fixed SH-groups[4]). The removal of the protecting skin accelerates respiration and enzymic activity, such as oxidative and hydrolytic processes, inducing the transition of the inhibitor to the accelerator, that is, fission of maleic acid into ethylene and carbon dioxide. Ethylene is evolved during ripening or the maturity period, gradually fading towards senescence. Its function appears to be dual. In the food-storing portion of the tuber it accelerates ripening by converting the starch granules into reducing sugars, and the insoluble pectin substances, principally protopectin, into a soluble form[3]. This is apparently accomplished by increased respiration, the selective activation of protoplasmic streaming and amylase, perhaps by the ready adsorption of ethylene by lyophilic colloids and consequent increased cell permeability. These changes exert a protective action on vitamin C and glutathione, while in other phases of plant development they lead to the degradation of proteins, fats and chlorophyll. However, on embryonic development ethylene has an inhibiting effect, suppressing the sprouting of potatoes and germination of seeds. This effect is temporary and apparently narcotic in nature, the germination proceeding unimpaired on removal of the gas[3]. Parallel with ethylene though not necessarily concurrently, other phyto-hormones, such as hetero-auxin and auxins, make their appearance, the former by the degradation of proteins and tryptophane, and the latter in the course of carbohydrate metabolism.

Sprouting coincides with tuber senescence, at which stage the nutrients, now made available, the physico-chemical reactions specific to colloids, as well as photosynthesis, all combine in forming a basis for the plant's morphological development. In this the alkaloidal glycoside solanine[5] plays a significant part, constituting apparently an intermediate stage between the carbohydrates and chlorophyll. The propagation of potatoes from excised 'eyes' and acceleration of sprouting following the skin removal point to the close association of the inhibitor with solanine; both are preponderantly concentrated in the 'eyes', though not entirely absent from the food-storing portion and skin of the tuber.

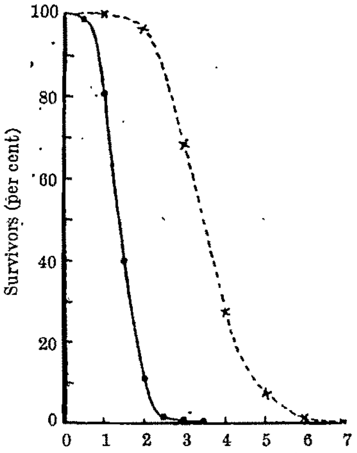
Influence of Colchicine Alone and Combined with X-Rays on Paramecium

THE influence of colchicine on cell division is now assumed generally as stoppage or freezing of mitosis; while Dustin and his collaborators supposed that colchicine stimulates mitosis. In spite of a large number of experiments on different organisms, the literature accessible to us failed, however, to disclose data relating to the influence of colchicine on Protozoa. We only found a short reference concerning the influence of colchicine on Paramecium[1].

To elucidate the production of division under the influence of colchicine we have carried out experiments on *Paramecium caudatum*. The use of this organism possesses several special advantages: (1) The dose of colchicine can be administered more uniformly to Protozoa than to other types of organisms, since every cell is uniformly immersed in the test solution. (2) The effect of the drug can be followed individually on a single cell, allowing precision in observation impossible on other test organisms. (3) Variations in the division rhythm are easily discerned and can be expressed in quantitative terms. (4) Contact with colchicine can be maintained uniformly for as long as is desirable and can be broken off at will by transfer of the organism to a normal milieu. (5) Colchicine can be readily combined with other treat-



Full line, treated in advance with colchicine; broken line, normal paramecia.

ments such as X-rays, As_2O_3, etc., either simultaneously or in succession.

The irradiation was carried out by means of a demountable X-ray tube which was operated at a tension of 18·5 kV. and 15 mA. using a copper anticathode. The window consisted of an aluminium foil of 30 μ thickness. The X-ray intensity at the distance of the irradiated object was 80,000 r./m.

Paramecia were cultivated in a mixture of two thirds standard hay infusion and one third soil extract prepared according to Pringsheim. From this basic medium three concentrations of colchicine were prepared (colchicine crystalline preparation, British Drug Houses, Ltd.). The solution designated C_1 contained 0·0005 per cent, C_2 contained 0·00025 per cent, and C_3 contained 0·000125 per cent of colchicine.

Single individuals from a given clone were transferred to fifteen drops of test solution and cultivated in the chamber of hollow-ground glass slides. To prolong the time between two divisions, the cultures were maintained at a relatively low temperature (20° C.). After twenty-four hours the number of animals in each chamber was counted and all transferred to fifteen fresh drops of the same medium for another twenty-four hours. The results of fifty experiments of this kind are summarized in the accompanying table. It is evident that C_1 concentration is lethal; on the other hand, C_2 concentration and, in more marked degree, C_3 concentration exert a stimulating effect on cell division. In C_3 solution the division rate is significantly greater than in the control medium.

For experiments with colchicine combined with X-rays, the Paramecia were maintained for forty-eight hours in the colchicine solution, then transferred to normal culture medium and therein irradiated. The irradiation was carried out in a hanging drop through a mica cover glass.

The lethal dose range in these experiments lies between 50,000 and 350,000 r., the half-value dose lying between 100,000 and 150,000 r. In earlier papers we showed that the lethal dose for normal Paramecia fluctuated between 200,000 and 700,000 r., the half-value doses lying between 300,000 and 250,000 r. These experiments show that the immediate lethal dose is considerably smaller—about 50 per cent—for Paramecia which received prior treatment with colchicine (see graph).

Influence of colchicine on the division rate of Paramecium

Counted after	Number of individuals in the different solutions			
	Solution C_1	Solution C_2	Solution C_3	Control
0 hr.	50	50	50	50
24 hr.	0	114	130	74
48 hr.	0	450	609	275

In experiments with arsenic acid (As_2O_3) it was shown that the colchicine pre-treated organisms do not differ from the controls in their susceptibility to arsenic. Colchicine pre-treated organisms were not different also from the controls in sensitivity to ultra-violet rays.

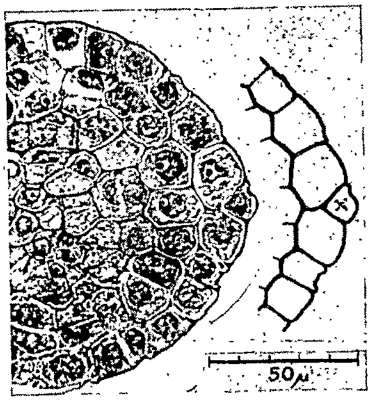
A Periclinal Division in the 'Dermatogen' at the Growing Point of Couch Grass, *Agropyron repens*, Beauv.

Except at the edges of young leaves, the 'dermatogen' cells in Dicotyledon shoot growing-points normally only divide anticlinally, but in many Monocotyledons they also divide periclinally where primordia are arising. That occasionally they may divide periclinally independently of leaf initiation was shown in a previous communication[1]. Since then, Miss E. A. Bindloss has mentioned (in a letter dated March 3, 1941) that she has also observed a similar situation in her material of maize plumules. It now seems that earlier, in Triticum, Rösler[2] had noticed a single example of dermatogen cells dividing periclinally without being involved in the production of a primordium. The following interesting case now deserves recording.

The photograph and accompanying cell-wall drawing show part of a transverse section of the growing point of couch grass, *Agropyron repens*, Beauv., taken



220 μ below the extreme tip, with a peculiar small cell (x) partly embedded in the dermatogen. The cell illustrated is not an isolated one, but is a member of a file about 330 μ long, commencing at about 150 μ from the tip and containing about thirty cells similar to the one photographed.

Presumably a single dermatogen cell divided periclinally, and subsequent transverse divisions have resulted in the file observed (five cell generations = 32 cells). At both ends of the file the last cells have become separated from the rest and have also sunk into the dematogen layer as though they have been accommodated by the adjustment of the neighbouring cells. At three points down the file, the cells on each side have divided periclinally where primordia are being initiated, but in no case are there periclinal walls in the cells of the file.

It would seem, therefore, that even in Angiosperms, isolated dermatogen cells may occasionally divide periclinally, and that the example described above represents one stage which may follow such a division, an example of which was previously seen in a single cell in maize.

The Highland Border Series in Bute

DURING a recent examination of a disused quarry ituated 750 yards west 10° south of Rothesay Pier, nd 1,200 yards north 15° west of the north end of he Kirk Dam, a band of limestone was observed on he north side of a broad east-west Permo-Carbonierous quartz-dolerite dyke. The limestone was ecorded by Gunn in 1884 on a 6-inch to the mile anuscript map of the Geological Survey, but it is ot shown on the published 1-inch to the mile map Sheet 29, 1892). It does not appear to have been escribed in geological literature, although it may ave been seen by Nicol[1], who made a passing eference to limestone in this part of the island.

The limestone, a fine-grained greyish-black type, ccurs in a band 7 feet thick, dipping south-south-east t 55°. It is associated with grey and black, someimes graphitic, cleaved shales containing further hinner beds of limestone. These shales form part f a band which has been traced for at least three iles to the south-south-west, parallel to and about alf a mile west-north-west of the Highland Boundary ault.

To the north-west the shales are bounded by a ide outcrop of grits which can be correlated with he Leny Grits of the Dalradian succession of Perthhire. On the evidence of graded bedding the grits an be demonstrated, at numerous localities, to resent their younger side to the shales, with which hey appear to be interbedded ; but this last point quires further investigation.

In the ground to the north-west the grits are llowed by a belt of phyllites which cross the island om Kames Bay to Etterick Bay. These form the uth-westerly continuation of the Dunoon phyllites nd like the latter contain thin beds of limestone. hey can be shown by means of graded bedding, as as been pointed out by Dr. W. J. McCallien[2], to be older than the grits to the south-east. They would seem, therefore, to lie on a different horizon from the Rothesay limestone and shales, from which, moreover, they differ considerably in character. Recent work suggests that the Kames Bay phyllites are also older than grits to the north-west and that they consequently occupy the core of an anticline.

On the basis of associated rocks, stratigraphical and structural position, the Rothesay limestone is regarded by the writer as equivalent to the Leny limestone at Callander, in which Dr. J. Pringle, who has since examined the Rothesay exposures and concurs in this view, has discovered fossils of Middle Cambrian age[3]. The Leny limestone has been correlated with the well-known Margie limestone forming part of the Highland Border Series of Angus and Kincardine[4]. This series includes rocks of both Cambrian and Ordovician age, and occupies a number of lenticular outcrops near the Highland Boundary Fault from Stonehaven to Arran. The Rothesay limestone and shales are considered to form a hitherto unrecorded example of one of these lenticles. When an opportunity for further search offers, it is hoped that they will yield, like the Callander rocks, fossils of Cambrian age.

The above observations were made during part of an investigation carried out with the aid of a grant from the Clough Research Fund.

Sulphur Springs of Cyprus

THE presence of sulphur springs in the island of Cyprus is a well-established fact, and several, such as the springs of Kalopanayotis and Ayoi Anargyroi, are widely used for treatment of internal and external diseases. It is therefore somewhat surprising that apart from casual samples sent for analysis abroad, no systematic survey has been undertaken so far. The handbook of R. Storrs and B. J. O'Brien, where a page on mineral springs has been reprinted without alteration from the earlier work of H. C. Luke and Jardine, contains but a few rather misleading data.

Some time ago I had the opportunity of investigating, on behalf of the Geophysical Institute of Cyprus, eight sulphur springs located at widely separated points of the island. These springs are only a part of the total occurrence, and the survey cannot, therefore, be regarded as exhaustive. It is nevertheless possible to draw certain conclusions inasmuch as the investigations covered the main sulphur spring localities of the island. They reveal the existence of two types of sulphur springs with distinctly different chemical composition, originating in different geological formations.

The springs of one group emanate from the igneous rocks of the Troodos range, mainly along the andesitic pillow lava zone. The springs of the second group have their source in the miocene Idalian formation, with their massive gypsum deposits.

The waters of the first group are characterized by their strong alkalinity and comparatively moderate salinity. Free sulphuretted hydrogen is not present, and although the water tastes strongly, no smell could be detected. It can be assumed that the sulphide is present as sodium sulphide, and this would also be in accordance with the *p*H value resulting from the hydrolytic dissociation of the corresponding amount of sulphide:

$$Na_2S + H_2O = NaSH + NaOH.$$

The handbook refers to sulphuretted hydrogen in the water of Kalopanayotis, and remarks that the chief salts of the springs are the chlorides of sodium and magnesium, sulphate of magnesium and carbonate of lime.

Analytical data for these springs of this first group are shown in Table 1.

TABLE 1

	Ayiasmata	Pelendri	Tiochou	Psammiacon
Temperature	23° C.	25·5° C.	19·7° C.	20·5°C.(Sept. midday)
Transparency	clear	clear	clear	clear
Colour	colourless	colourless	colourless	colourless
*p*H	11·3	11·4	11·6	11·7
KNO_3 (mgm./l.)	1·5	—	—	—
KCl	4·5	9·1	26·0	61·5
NaCl	335·3	207·0	722·6	698·2
Na_2S	13·1	23·4	56·1	63·1
Na_2SO_4	31·3	29·1	43·5	36·9
Na_2CO_3	31·5	55·5	161·0	126·1
$CaSO_4$	256·3	26·6	9·2	5·8
$MgSO_4$	0·9	—	—	—
$Al_2(SO_4)_3$	1·5	—	1·1	1·1
Total Salines	677·9	351·3	1,019·5	992·7
H_2SiO_3	10·1	25·6	64·4	69·6
HBO_2	2·9	4·1	11·2	7·8

The waters of the second group are slightly acid (almost neutral), and are nearly saturated with gypsum. The fact that these springs have their source in the gypsum rocks of the Idalian series explains satisfactorily the high calcium sulphate content. The water contains sulphuretted hydrogen as well as carbonic acid and bicarbonate, and smells and tastes of hydrogen sulphide. The presence of sulphide is probably due to the reduction of calcium sulphate with subsequent freeing of sulphuretted hydrogen through action of the carbonic acid.

Analytical data for the four springs of the second group are given in Table 2.

P.O.B. 30,
Larnaca.
May 29.

Temperature of Flame Gases

IN internal combustion engines the temperature of the flame gases is inferred from pressure and volume measurements and is therefore a measure of their mean molecular translational energy. In open flames, however, the temperature is generally assumed to be that acquired by a thermometric substance immersed in them (after correction for radiation loss). But the temperatures shown in the table below indicate that this requires further consideration. These temperatures were measured by means of very fine platinum-rhodium wires (0·0005 in. diameter) and quartz-covered platinum-rhodium wires (0·0005 in. overall diameter) during the pre-pressure period in large closed-vessel explosions[1]. No correction for radiation loss has been applied to them. The combustible gas-air mixtures were at atmospheric pressure and were thoroughly mixed before ignition by an electric spark.

Percentage combustible gas in mixture	Temperature (°C.) measured by		
	Quartz covered wire	Plain wire	Difference
20% CO*	1,210	1,420	210
25% CO*	1,350	1,650	300
29·6% CO*	1,470	1,850†	380
55% CO*	1,350	1,350	0
60% CO*	1,260	1,260	0
7·5% CH_4	1,250	1,440	190
8·5% CH_4	1,320	1,600	280
9·47% CH_4	1,380	1,730	350

* The carbon monoxide contained 1% hydrogen.
† Slightly extrapolated.

There would have been little or no difference between the temperatures measured by the two wires had the flame gases been just hot normal gases. But as has been shown, flame gases contain a long-lived latent energy (probably resident within a proportion of the newly formed tri-atomic molecules) and in virtue of this an abnormal dissociation may obtain in them. It would appear, therefore, that a thermometric substance immersed in flame gases may be heated as a result of:

(1) their true temperature (proportional to their mean molecular translational energy),

(2) the unloading of latent energy upon its surface, and

(3) recombination of the abnormally dissociated products upon its surface, provided that this is of a type (like platinum) which promotes surface combustion.

The large differences between the uncoated and quartz-coated wires must be due mainly to (3). In the case of the 55 per cent and 60 per cent carbon monoxide mixtures it will be noted that there is no difference between the temperatures measured by the two wires, and in these cases it must be supposed that the abnormal dissociation is suppressed by the large excess of carbon monoxide.

SABETHINE MOSQUITOES OF THE AMERICAS

By DR. JOHN SMART

Department of Entomology, British Museum (Natural History)

YELLOW fever exists in two forms which differ epidemiologically, the well-known classical form of the disease and the more recently discovered jungle yellow fever. In both cases the virus is transmitted to man by the bite of an infected mosquito.

In the ordinary form of yellow fever the mosquito acquires the virus by biting a man suffering from the disease. The vector of this form of the disease is the tropicopolitan tiger mosquito, *Aëdes* (*Stegomyia aegypti* (Linn.) (= *Stegomyia fasciata* (Fabr.)), which is a domestic species in that it tends to breed in collections of water accidentally or deliberately created by man in and around his dwellings. Several other species of mosquitoes, mostly, but by no means exclusively, of the same genus, are known to be capable of transmitting the virus under experimental conditions, but, for various reasons, they were, until recently, not regarded as of any significance as vectors in a state of Nature. Effective means of controlling the tiger mosquito were evolved and the Rockefeller Foundation[1], which carried out a vast amount of work on yellow fever, stated at one time that, prior to 1929, it was believed that it might be possible to eliminate the disease completely. In addition to the control of the disease by the application of anti-mosquito measures, successful vaccine treatment has now also been evolved.

In 1932, however, as reported by Soper and his co-workers[2], a different epidemiological type of yellow fever broke out in a locality in Brazil. In this outbreak, and in others that followed in other localities, no trace of the tiger mosquito could be found; the outbreaks occurred in rural localities in forest areas. In these outbreaks man was generally infected only while in contact with the jungle or forest, and this new form of the disease became known as jungle yellow fever. A search had to be commenced at once to discover the actual or probable vectors of the virus in this new form of the disease as well as the source whence the virus came at the commencement of these isolated outbreaks.

Prior to the discovery of Stokes and his co-workers[3] in 1927 that the yellow fever virus could be successfully transmitted to the rhesus monkey, no experimental animals or wild animals capable of harbouring the virus were known. Since that date it has been discovered that a number of rodents and other animals react to and can harbour the virus. These discoveries simplified greatly the search for new mosquito vectors by providing a means whereby the presence of the virus in a mosquito could be detected by direct biting experiments and by indirect inoculation methods. They also pointed to the animals of the jungle and forest as a potential reservoir for the virus from which it could periodically escape into human communities by the bite of some jungle mosquito that had previously bitten an infected ungle animal.

To cut a long and exciting story short, yellow fever virus was detected in wild animals and, in 1928, Shannon and his co-workers[4] discovered the presence of the virus in wild-caught jungle mosquitoes. These workers were able to demonstrate actual transmission of the virus to monkeys by two species of wild-caught jungle mosquitoes, *Aëdes* (*Finlaya*) *leucocelænus* D. and S. and *Hæmogogus capricornii* Lutz, and, in addition, they proved the presence of the virus in a number of species of jungle mosquitoes belonging to the group known as the Sabethine mosquitoes.

The Sabethine mosquitoes are mostly rain forest insects and, owing to their habitat, relatively few specimens are found in collections unless they have been especially sought. The information about them was somewhat sparse, and Shannon and his co-workers[4] had to admit that it was "impracticable during this preliminary study to separate the sabethines by species". Edwards[5], in 1932, catalogued 109 species from the Americas and indicated that information about the larvæ was available in the case of fifty-one species. It was obvious that a monographic treatment of the group was urgently needed.

It is appropriate that this need should have been appreciated, and the work carried out to fill it, by two workers in Brazil. J. Lane (Istituto de Higiene da Universidade de São Paulo) and N. L. Cerqueira (Serviço de Estudos e Pesquisas sobre a Febre Amarela) have recently published a lengthy paper —"Os Sabethineos da America (Diptera, Culicidæ)". (*Arqu. Zool., Estado São Paulo*, 3, pp. 473–849, Oct. 1942, in Portuguese)—in which they have provided a systematic revision of the group, amply illustrated and containing a considerable amount of information on the biology of its members.

Lane and Cerqueira deal with 150 New World species and one variety; they describe the females of 147 species, the males of 122, the pupæ of fifty-three and the larvæ of eighty-nine species. Thirty-two of the species are described as new. Full synonymy is given with copious notes on distribution; keys to the females, males, pupæ and fourth-stage larvæ are provided. Altogether there are 219 pages of letterpress and 76 pages of figures, of which there are a total of 450. The work involved much breeding of species in the laboratory, and some of the species described are known from adults bred from larvæ, but have not yet been caught on the wing in a wild state. The data on distribution were greatly helped by the examination of some 260,000 specimens of Sabethines collected by the Serviço de Febre Amarela and later by the Serviço de Estudos e Pesquisas sobre a Febre Amarela organized by R. C. Shannon.

Edwards[5] regarded the genera that constitute the Sabethines as a group within the tribe Culicini of the sub-family Culicinæ of the family Culicidæ. Lane and Cerqueira follow certain other authors and treat the group as a tribe, Sabethini, distinct from, but of the same taxonomic status as, the Culicini. They distribute the American species among five genera and seventeen sub-genera. The fifty-nine species of Old World Sabethines catalogued by Edwards[5] in 1932 were distributed among three genera and six sub-genera. None of the genera is common to both the Old and New Worlds.

The adult Sabethines have long been known for the beauty of their coloration and ornamentation, and of the different genera the typical genus Sabethes, which is confined to the Neotropical region, is probably the most familiar. In this genus the usual coloration is a mixture of dark blue and shining white, but their most remarkable feature is the 'paddles' that are borne on the mid-tibiæ and sometimes on the fore- and hind-tibiæ as well. These 'paddles' are formed by a dorsal and a ventral fringe of long erect scales which may extend beyond the tibiæ on to the upper part of the tarsus. The function of these paddles remains uncertain though they undoubtedly draw the eye to the individual mosquito when it is in flight.

The adult Sabethines are diurnal and the females of most species bite both man and horse; there is a record of a female biting a lizard. The males are not known to swarm, and Lane and Cerqueira suggest that the sexes may be attracted to each other by their brilliant coloration in daylight. The male of *Limatus durhami* Theob. has been observed resting on a tree trunk with the proboscis bent upwards, thus exposing to view a bright blue patch of scales on the underside; it is suggested that many of the other forms of ornamentation may be correlated with some habit that brings them into use for purposes of display.

The larvæ are found in the water gathered in the axils of the leaves of various water-holding plants (Bromeliaceæ, Araceæ, Muscaceæ, etc.), in water gathered in fallen leaves, husks of fallen fruits, tree holes, bamboo holes and other similar water-holding situations that abound in the tropical rain-forest. *Limatus durhami* appears to be unique in that it breeds in water collected in tins and broken vessels on abandoned rubbish tips as well as in water in fallen leaves; though thus occurring in peri-domestic breeding places, this species does not occur in sufficient numbers to become a pest. Some species are restricted to special breeding habitats. *Weomyia (Menolepis) leucostigma* (Lutz) breeds only in the axils of the leaves of 'tabua' (Typhaceæ), and the larvæ of *Weomyia (Dendromyia) melanocephala* D. and S. are found in the leaf-axils of 'tabua', 'taioba', 'tinhorão' (Araceæ) and occasionally in the internodes of bamboo. The insectivorous plants that hold fluid in their leaves harbour the larvæ of some species.

The abundance of the species does not seem to vary much with the seasons as is the case with Anophelines and Culicines in the same district. Their seeming rarity is, of course, obviously due to the wide dispersal of their breeding places. Their total numbers over a wide area are probably very large, exceeding the populations of other mosquitoes that happen to be restricted to a domestic or semi-domestic breeding habitat, though these latter species might appear in considerable concentrations in some small settlement in the jungle and so give the impression of being present in much larger numbers than the jungle-breeding Sabethines.

Sanitarians and others concerned with the battle against yellow fever should now find themselves armed with a satisfactory tool for identifying the Sabethine mosquitoes of the New World, while systematists interested in the Culicidæ will thank the authors for their services in collecting the available information, adding much that is new thereto, and in presenting it in a clear and pleasing format.

The authors have expressed their intention to deposit paratypes of certain of their new species and other material in the British Museum (Natural History) as a return for the assistance rendered to them in the prosecution of their work by the late Dr. F. W. Edwards of the Department of Entomology.

FORTHCOMING EVENTS

Saturday, September 4

BRITISH PSYCHOLOGICAL SOCIETY (at Tavistock House, Tavistock Square, London, W.C.1), at 2 p.m.—"On the Problem of Representative Sampling of the Population".

Thursday, September 9

PHYSICAL SOCIETY (COLOUR GROUP) (in the Lecture Theatre of the Science Museum, Exhibition Road, South Kensington, London, S.W.7), at 2.30 p.m.—Mr. J. B. Reid: "A Review of the Theory of Colour Photography".

Friday, September 10

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. Svein Rosseland: "The Pulsation Theory of Cepheid Variables" (George Darwin Lecture).

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN MATHEMATICS in the Coventry Technical College—The Director of Education, Education Offices, Coventry (September 7).

ANIMAL HUSBANDRY OFFICER—The Secretary, Norfolk War Agricultural Executive Committee, Sprowston, Norwich (September 11).

LECTURER IN MINING (COAL)—The Secretary, The University, Edmund Street, Birmingham 3 (September 18).

LECTURER IN EDUCATION, PSYCHOLOGY AND SOCIAL PHILOSOPHY—The Principal, South-West Essex Technical College and School of Art, Forest Road, Walthamstow, London, E.17 (September 10).

PRINCIPAL OF THE MUNICIPAL TECHNICAL COLLEGE—The Director of Education, Education Office, St. Helens (September 11).

TEACHER OF METALWORK in the Junior Technical School—The Principal, Technical College, Church Street, Barnsley (September 13).

ASSISTANT MASTER TO TEACH MATHEMATICS in the Junior Technical School and to part-time students up to Higher National Certificate standard, at the Willesden Technical College, Denzil Road, N.W.10—Dr. E. Davies, Education Office, Vernon House, Willesden Lane, London, N.W.6 (September 15).

HEAD OF THE ENGINEERING DEPARTMENT of the South-East Essex Technical College and School of Art, Longbridge Road, Dagenham—The Chief Education Officer, County Offices, Chelmsford (September 18).

INSPECTOR OF MINING SUBJECTS (Reference No. C.1843), and a WOMAN INSPECTOR OF TECHNICAL TRAINING FOR WOMEN (Reference No. C.1844)—The Ministry of Labour and National Service, Central (Technical and Scientific) Register, Alexandra House, Kingsway, London, W.C.2 (quoting the appropriate Reference No.) (September 20).

PHYSICIST TO THE RADIOTHERAPY DEPARTMENT—The Secretary, University College Hospital, Gower Street, London, W.C.1 (September 27).

CHAIR OF SOCIAL MEDICINE—The Secretary, The University, Edmund Street, Birmingham 3 (March 1).

LECTURER IN THE DEPARTMENT OF ELECTRICAL ENGINEERING of the Cape Technical College, Capetown, South Africa—The Secretary, Overseas Manpower Committee (Reference 1021), Ministry of Labour and National Service, Alexandra House, Kingsway, London, W.C.2.

BIOCHEMIST—The Secretary, Institute of Research for the Prevention of Disease, 117 Grove Street, Liverpool 7.

BIOLOGY MASTER, mainly for a new Pre-Agricultural Course in the Day Technical School—The Principal, Maidstone Technical Institute, Tonbridge Road, Maidstone.

THE CHALLENGE OF PEACE

IN his address last year at the Conference on Mineral Resources and the Atlantic Charter, arranged by the British Association, Sir Stafford Cripps struck a note that has been reflected more frequently in the speeches of American leaders than those in Great Britain. "We are fighting," he said, "for a moral and not merely for a material issue. Though our plans must be scientifically prepared there must be behind them the inspiration of our most deeply religious convictions." That note has been struck repeatedly in the speeches of Mr. Henry Wallace, of President Roosevelt and of Mr. J. G. Winant. It was clearly to be heard in the address broadcast by the Archbishop of Canterbury during the Day of National Prayer held on September 3 which marked the fourth anniversary of the outbreak of the War. Dr. Temple stressed the importance and urgency of preparedness for the tasks of peace, in themselves no less arduous than those imposed by war. The duties which will face us then, he said, will demand a spiritual approach.

The topic forms a main theme of Mr. H. Agar's recent book "A Time for Greatness", and in a different guise it is encountered in an article in the American periodical *Fortune*. That article touches simultaneously on a note that was very marked in the closing sessions of the House of Commons before the recess. The very success of the War in recent months and the growing conviction that victory was coming into sight had aroused concern as to our readiness to meet the problems of peace, a concern that was obviously fostered by the Government's refusal to take decisions and announce its policy on matters which in the Uthwatt Report, the Barlow Report or the Scott Report had long been before it. "The real danger to American civilization," wrote the editor of *Fortune*, "is a danger not of war but of peace. It is the danger that we may prove unable to make of peace a higher and more effective expression of that civilization than we have made of war. The danger is that we shall find no national purpose—except war—capable of evoking our greatest energies."

Conditions differ in the two democracies, but within the House of Commons and in the country at large there are many who would unhesitatingly subscribe to this new declaration of the need for a moral equivalent of war as being fully as pertinent to Great Britain as to the United States. The article sets fairly before the American reader the three great challenges to American civilization which challenge Britain no less: the threat of war to civilized life and the need to replace it by some such methods as implementing and making permanent the United Nations, an Anglo-American union, or the method of international law; the challenge of the machine and the solution of the problem of distribution which holds up the raising of standards of living throughout the world; and the philosophical challenge of the meaning of life—the rediscovery of faith.

These great postulates are challenges which know no national frontiers. They reach to the foundations of our common civilization, and in meeting them out of the richest of their common experience and heritage, it may well be that Britain and America may find or renew a spiritual unity even closer than the physical unity which has brought them in sight of victory. Certainly such a spiritual unity affords the only enduring basis for whatever constitutional developments may flow from turning to the service of the needs of rehabilitation and reconstruction the agencies which we have had to bring into being for the effective service of the war effort.

While we may well welcome the evidence that Americans are being called by their own countrymen to fundamental thinking on the moral and vital issues which must be faced if they and we are to win the peace, there is no less need for fundamental thinking on this side of the Atlantic. Mr. Lionel Curtis's "Faith and Works" is an honest attempt to elucidate these issues from the British side, emphasizing the moral basis of any attempt to eliminate world war and the minimum constitutional changes which in his view would be sufficient for that purpose*.

Mr. Curtis takes up the position which Lord Lothian took up in his Burge Lecture in 1935, that the essential cause of world wars is the fragmentation of human society into more than sixty sovereign States. His basic point is that we should recognize that Great Britain standing alone is no longer able to ensure the security of the Commonwealth as a whole, or even that of the British Isles. It can no longer provide the security which the United Kingdom was able to provide in the nineteenth century when, as Prof. E. H. Carr observes, "the British fleet not only guaranteed immunity from major wars but policed the high seas and offered equal security to all".

There can be no doubt that Mr. Curtis is right in directing attention to this fundamental, if unpalatable, fact, though recognition of this and also of the truth of Washington's words, which he also quotes, "Influence is not government", does not necessarily lead to the view that the problem of security for the United Nations will only be solved when the peoples of the American and British Commonwealths have merged their resources under one organic government charged with their common defence. Mr. Curtis does not go all the way towards federalism, but his argument carries him far along the path towards the formulation of definite constitutional proposals as opposed to the functional growth which has been advocated by Prof. Mitrany in a recent paper issued by the Royal Institute of International Affairs. Mr. Curtis, however, forces us to face the fact that the Government of Great Britain will not be in a position to give again to the peoples of the occupied countries like Belgium, Holland and Norway such a guarantee as we gave to Belgium. We can only invite them to join in discussions as to how the burden of a common defence could be shared.

Proposals for the re-establishment of European and of world order and for the maintenance of peace must start from this point. Mr. Curtis's proposals are equally inspired by the belief that no duties should be entrusted to a central government which could be discharged effectively by a local or regional government, but that where duties are entrusted adequate power should also be provided. None the less, he strays a long way from the functionalism or the evolution and adaptation to the purposes of peace of the organisms set up to serve our war needs which now seems to be the main approach to the problem favoured by those actively concerned with the task of reconstruction.

Mr. Curtis insists that peace and social reform are two inseparable ends. Social reform and a higher standard of life cannot be achieved unless peace is firmly established among the nations; and we cannot establish peace unless national governments are really equipped to cope with social reform. His argument that the real obstacle to social reform is that national governments have so much to do that they cannot keep pace with the changes that a mechanized age demands, finds a pertinent illustration in the present impasse in Great Britain arising out of the Government's delay in implementing the decisions and policy called for in the field of physical reconstruction and planning. If it were possible to relieve national governments of the task of maintaining peace and to entrust it to an international government, the pace and efficiency of social reform might reasonably be expected to quicken.

Whether the line between international and national functions can be drawn as clearly as Mr. Curtis suggests is another matter; even in social reform, such matters as health and nutrition can scarcely be determined by independent national action alone. He would leave to the national governments the last word on the incidence of taxation between one citizen and another, on tariffs, on industry and commerce; international government would, however, be given power to make the security of all the nations it has to protect a first charge on all their resources, material and human; the burden of the revenue required for the common defence would be distributed between the nations defended in proportion to their taxable capacity as ascertained by a judicial committee of experts. Beyond this any international government charged with the task of averting war should have the power to hold under its own flag a merchant marine large enough to secure its transport needs in war, and such government should also be given complete control of all aviation between the nations united and charged with the duty of creating an adequate service. Finally, it must have power to control dependencies not ripe for responsible government.

As to the extent of the defence association, Mr. Curtis appears to have in mind one embracing Great Britain and one or more of the Dominions, the United States and the democracies of Western Europe. The international government should, he urges, be responsible, not to national governments but to the peoples they represent. Essentially he argues for an instrument selected and shaped for the particular purpose which it is to serve and free from commitments which might dissipate its energies or confuse the issues. He insists that we should not treat instruments and methods as ends in themselves and lose sight of the ends for which they were devised.

---

* Faith and Works. By Lionel Curtis. Pp. vi+120. (London: Oxford University Press, 1943.) 2s. net.

The insistence on moral values and the note of pragmatism which is sounded throughout give Mr. Curtis's pamphlet a real value in discussions on the form which the organization of world government must take. Whether we accept his conclusions or not, he emphasizes some of the realities which must be faced in any solution, and different as are the conclusions he draws from those drawn by Sir Frederick Maurice in his recent study of "The Armistices of 1918" they are a striking complement to the latter. In both, indeed, there is the same note of urgency—Sir Frederick Maurice's first point is that a request for an armistice may come as unexpectedly as any event in war—and both insist on the need for foresight and preparation and the necessity of maintaining for an indefinite period the power to enforce the will of the United Nations, or in other words to maintain the peace.

Sir Frederick Maurice points out that the preparation necessary if the terms of armistice are to be satisfactory should include arrangements for the effective occupation of enemy territory until satisfactory terms of peace are assured ; and, as corollary to his second conclusion as to the maintenance of effective military force, he points out that it is important that an early decision should be reached as to the size and distribution of the forces which the Allies should maintain. A programme should be prepared for the gradual reduction of our forces and announced to the Services at the earliest possible date, and no political or private interests should be allowed to interfere with the orderly execution of this programme.

It may well be asked whether such a programme can be drawn up except on the basis of such discussions as are envisaged by Mr. Curtis. The fatal mistake of unilateral disarmament must not be repeated, and the indispensable measure of agreement on this point between Great Britain, the United States and the U.S.S.R., if not with others of the United Nations, might well be the prelude to some such organization as Mr. Curtis suggests, though probably less formal, and based on governments, not on the individual citizens. Sir Frederick Maurice's third conclusion, that the preparation of terms of armistice, the supervision of the execution of these terms, and the solution of the many and varied problems which will arise after the signature of the armistice raise questions different in nature and kind from those which are brought up by the preparation of treaties of peace, again emphasizes the necessity for formulating plans and reaching agreement on peace aims in advance. Preliminary studies must be made during the War and a nucleus of the necessary organization established.

His final conclusion that the Allies, if they are to secure their declared war aims of disarming the aggressors, must provide themselves with the necessary means, once again emphasizes the necessity not only for adequate force but also for agreement as to its constitution. Here he suggests that air power may provide a solution, and that it should be our object to deprive our enemies of all aircraft, military or civil, and to control their disarmament by an allied air force until such time as more permanent arrangements for the prevention of aggression can be established. He sees in the trial of such an air force composed of contingents of the air forces of the Powers, members of the international authority, to control our enemies in the interval between the signatures of armistices and the ratification of treaties of peace an opportunity to experiment which if successful could be made part of a permanent organization for the preservation of the peace of the world.

There may well be less difference than appears on the surface, therefore, between the proposals of Mr. Curtis and the conclusions reached by Sir Frederick Maurice. The latter is strikingly in line with pronouncements which have already been made by members of the Government in both Great Britain and the United States. In his important Guildhall speech last February Mr. Herbert Morrison contemplated the creation in due time of a genuinely representative world political association. Like all others he emphasized the necessity of any such association possessing a force fully sufficient to achieve its agreed purposes and to restrain those who would impede them, but he spoke also of how constructive and systematic thought on the problems of supply and raw material allocation, of relief and rehabilitation was creating the very stuff and content of post-war international relations. On the American side, Mr. Cordell Hull has been equally explicit as to the necessity for creating some international agency. Again, the American Commission to Study the Organisation of Peace has both recognized the spiritual and ethical basis on which any form of world organization must rest and stressed the necessity for new institutions, world-wide and regional, to perform services which can no longer be left to each State acting as a separate unit.

One well-marked school of thought looks to the development of Europe's public utilities to encourage a fuller sense of Continental unity. Mr. Amery, rejecting the idea of federation for the British Empire, although contemplating some regional or federal developments into larger units by the smaller countries of Europe, looks to closer working arrangements between Britain and the Dominions and the development of the Imperial Conference system. It will not escape notice that Mr. Churchill paused very deliberately for consultations in Quebec before proceeding to the United States on his latest visit to America. If we are to exclude federalism, on defence grounds alone the facts emphasized by Mr. Curtis will compel us to establish some working executive of defence which can scarcely be limited to the Empire, and it will be at least essential for all the British nations to be ready to take commitments in common council.

One suggestion, advanced by Sir Edward Grigg, is for a series of Empire regional councils, but more than this will clearly be required however much such a development might assist us to surmount some of the geographical difficulties. Meanwhile, Mr. Richard Law has hailed the Hot Springs Conference on Food and Agriculture, with its establishment of an interim Commission to carry on its work, as the birth of the United Nations. The United Nations Relief and Rehabilitation Administration is another notable step in the same direction, and in the Combined Raw Materials Board, the Combined Food Board and the Shipping Adjustment Board we have other instruments which may serve as a basis for world co-operation after the War. More is, of course, required. Currency plans are as yet embryonic, and only the most tentative approach has been made to the vast problems of international trade and exchange; and there are no signs at all that anything of the nature of a general staff for peace has yet been set to work in accordance with the important suggestions made last year by the Netherlands Ministers for Economic Affairs and for Colonies.

The arguments advanced by Mr. Kerstens and by Dr. van Mook have lost nothing in weight since last autumn, and though it is clear from Mr. Churchill's broadcast last March that the Government is thinking about these problems in general terms the time is fast approaching when some more definite assurance may well be demanded that the Government is ready not only with the armistice plans discussed by Sir Maurice Hankey but also with concrete proposals for dealing with the grave problems of order and reconstruction which must be handled before any permanent form of world association is possible. The vital thought and study in these matters are required now if we are to be ready in time, and no pre-occupation with the conduct of the war can justify postponement of the facing of these tasks, more difficult and more arduous than any the leaders of the United Nations have yet encountered. Whether they prove equal to those searching demands, whether they can provide the leadership which will find and secure acceptance of a solution of these difficult problems of world order depends on whether they bring to their task not only the realism and vision on which Mr. Curtis insists, but whether also they have the imagination to take their peoples into their confidence and to make them understand the conditions and the sacrifices involved, so that neither peoples nor leaders shall again be guilty of the moral slackness and indulgence that, as Sir Geoffrey Knox has just pointed out, played so large a part in robbing us of the fruits of victory after the War of 1914–18 was concluded.

Unless both leaders and peoples alike have the courage to face the full facts and the resolution not merely to shape the appropriate instruments but to use them with imagination and discipline, our hopes of a better world order and an enduring peace are vain indeed. For whether that world order comes by evolution or by revolution in the physical world, it may well involve a moral revolution, for it is based on men and women and human values: courage, unselfishness, and magnanimity, firmness of purpose and clarity of vision, truth and honesty—these are the ultimate foundation.

SCIENCE, RELIGION AND EDUCATION

Science, Religion and the Future

Discipline for Democracy

By T. V. Smith. (Weil Lectures on American Citizenship.) Pp. xiv+137. (Chapel Hill, N.C.: University of North Carolina Press; London: Oxford University Press, 1942.) 12s. net.

THE "conflict between religion and science", to quote from the title of J. W. Draper's book published in 1874, which was widely read sixty years ago, means practically for most of us the battle between believers in the Biblical accounts of creation and believers in the theory of evolution. That contest has abated its intensity, but there is evidence that it still exists, though in milder forms, in places much nearer than Tennessee. This is the point of departure chosen by Dr. C. E. Raven, regius professor of divinity in the University of Cambridge, in a vigorously written book which has recently appeared. Insisting on the necessity of outspokenness, he declares that "while the Christian religion as professed by the churches still clings restrictively to a *Weltanschauung* that is demonstrably unscientific, to superstitions that violate the intelligence and to conduct that shocks the morality of modern man, no such consistency as is essential can be expected. To be a Christian, or at least to hold official position in the churches, is to accept formulæ parts of which can only be explained by being explained away, or else to keep secular knowledge and religious belief in permanent estrangement". Dr. Raven gives a characteristically lively account of the conflict which began on June 30, 1860, with the encounter of Huxley and Wilberforce at the Oxford meeting of the British Association, and which "made overt and abiding the cleavage between traditional Christianity and progressive science".

The author's main concern, however, is not with the conflict as a historical fact, but with what he holds to be "its tragic consequences in the bewilderment, corruption and destruction of mankind". For, says he, "the outbreak of the struggle in 1939, though it plainly demonstrated the need and the opportunity for the assertion of an integrating, and, as many recognized, authentically Christian ideal, found the Church theologically and ethically divided and in consequence practically impotent". So it was left to "the bright superficiality of the Brains Trust to supply the public with answers to its problems and guidance in its search for a philosophy of life". The remedy, for which the author puts in a powerful plea, is the unflinching application of the scientific method to every human interest. It is largely, he says, the acceptance of psychology as a science, complementary as this acceptance is to the stress upon the subjective and relative elements in the new physics, that "has led the younger men to claim all organized knowledge as the scientist's proper province, and to consider how methods can be developed for the scientific study of ranges of experience not amenable to the technique appropriate to material objects in a laboratory". The scientific method is not the sole perquisite of workers in laboratories, but may be applied "as rigidly and honestly in their proper fields by historians and even theologians". Needless to say, the author strongly dissents from the position that scientific method necessarily involves measurement. Throughout the book the author obviously tells the reader exactly what he thinks, with a minimum of care for official discretion. He writes not only as a distinguished theologian, but also as an ardent field naturalist.

All things considered, one need not wonder at finding points of contact between Dr. Raven's lectures and Sir Richard Gregory's Conway Memorial Lecture delivered last March. It is perhaps permissible to say that the former writes as a scientific humanist and the latter as a humanistic scientist, and that between the two there is no yawning gulf. Sir Richard, for example, recalls incidentally the story of Joshua's treatment of Jericho, remarking that Hitler is doing the same to-day on a vastly larger scale. "Such, however," he proceeds, "is the reverence attached to Holy Scripture that in a 'Lift up your Hearts' talk with which a B.B.C. clergyman opened the day a short time ago, he told the story as an example of a warrior following a Divine command! This is a kind of religious teaching against which both heart and reason revolt." Sir Richard's general position is that while science cannot deny the fact of religion or the influence of religious faith, it may examine them and seek to understand them. "With increase of knowledge, much of the mystery upon which religious beliefs are based is revealed and new concepts have to be created to satisfy the rational mind. It is when there is a refusal to recognise this essential function of progressive knowledge that conflict arises between religion and science." He reasonably claims that the changes associated with the meaning of modern civilization are results of scientific discovery and mechanical invention, and that progress in these has never been encouraged by religious teaching. He has no quarrel with religious teaching, including Christian teaching, except when it is intolerant, and he regards it as intolerant when it ignores or even denies the virtues of other great religions, adherents of which are at this moment fighting on our side for a certain way of life upon which they place an equal value.

The remaining book of those here selected for notice is also the permanent record of a lecture, one of the Weil Lectures on American Citizenship given at the University of North Carolina. The author, who writes with equal charm and candour, is Prof. T. Vernor Smith, of the University of Chicago. As eternal vigilance is the price of liberty, so, says the author in effect, is strict discipline the price of democracy. He makes very clear what we are fighting for. What a burden is laid upon the spirits of free men, he cries, to have to do evil that good may possibly be restored! "For the whole world to sink as low in spiritual tone as Naziism has sunk would be to lose next to all that civilisation has gained. It would be to lose truth to its boasted subversion, a propaganda diabolically intent upon prostituting goodness and beauty no less than truth to the poison of power." Keeping the three absolute values in view, he proceeds to deal with science as the discipline of truth, art as the discipline of beauty, and (strange as it may sound at first) politics as the discipline of goodness. Such is the discipline to which democracy must strive to submit.

Democracy is unworkable except by "agreement among equally able and equally honest seekers after truth"; and, says the author in a significant passage, the simple fact is that religion has no method of resolving differences and of begetting agreement. For that reason he rejoices at "the wise separation of Church and State" in the United States. Toleration is the only solution of the differences between Methodists and Baptists. For reasons that lie in history, Unitarianism is more important in New England than in Old England, and the author quotes the witty remark that Unitarianism proclaims "the fatherhood of God, the brotherhood of man, and the neighbourhood of Boston". Generalize that saying, and you have the reason why religion can never be a reconciler of differences. Science, not religion, provides "the strategy of agreement". Some citizens (men of science) "indulge" in it and enjoy its roots, more citizens (teachers and the like) "participate in it and smell its sweet flowers", and all citizens are beneficiaries of it and enjoy its fruits. Thus far science, with its disinterested and relentless pursuit of truth. The searchers are few, but the beneficiaries are all mankind.

Yet the author departs from the hard counsel of W. K. Clifford, that it is wrong "always, everywhere, and for every one, to believe anything on insufficient evidence". Truth is not the only value which defines civilization. Civilization would be infinitely poorer if it were so—witness the classical instance of Charles Darwin, who lived to lose all his early interest in poetry, pictures, and music. Science contracts the life of imagination. Art expands it, up to the acceptance of all which the mind's eye can discern. Again we have the citizens (artists) who indulge in art and enjoy its roots, more (parents and teachers and trainers) who participate in it and smell its sweet flowers, and all citizens who are beneficiaries and enjoy the fruits so vividly described by the author.

What of politics, as the discipline of goodness? Reduced to simple terms, politics are just the art or the science of settling disputes. Domination is the only alternative when equally honest men are in deep difference as to what is good. Either one side gets its complete way—which is dictatorship—or a new way is devised in which each gets enough of what it wants to observe a truce in the spirit of sportsmanship—which is democracy. Here the author gives a shining example of political compromise at work. The American Union is a system of two incommensurable but not incompatible principles, the principle of compromise for the settlement of all weighty disputes, and the principle of no compromise for the protection of all private principles compatible with public order—such as religious principles. The author will not allow the finger of scorn to be pointed at the politician, and he shows that all citizens of a democracy enjoy more fruits than they themselves create.

The functions of science, art and ethics in a well-ordered democracy, and incidentally the treatment of religious and other private convictions, are trenchantly discussed in this remarkable book. The author should become better known in Great Britain.

T. RAYMONT.

JOHN GILBERT: ORNITHOLOGIST

Strange New World

The Adventures of John Gilbert and Ludwig Leichhardt. By Alec H. Chisholm. Pp. xxii+382+25 plates. (Sydney and London: Angus and Robertson, Ltd., 1941.) 12*s*. 6*d*.

THIS book tells of two journeys of discovery, the one free of hazard and successful beyond expectation: the other always on the brink of disaster, ending in stark tragedy. The first adventure is that undertaken in 1938 by Alec Chisholm in search of personal relics of John Gilbert, the second is that of Ludwig Leichhardt, who in 1844 set off over the Darling Downs to reach Port Essington. The name of John Gould "the Bird Man" is known all over Australia in association with the wonderful bird fauna of Australasia. John Gould is a substantial figure whose achievements are amply chronicled in the "Dictionary of National Biography" and other works of reference. John Gilbert, though almost equally well known as a name in Australia, was, until Chisholm's voyage of discovery ended in triumph, no more than a name to anyone, for next to nothing was known of the man himself. How Chisholm finally discovered Gilbert's note-books and diaries in the possession of Drs. Geoffrey and Alan Edelsten, grandsons of John Gould's eldest daughter Eliza, is a story of happy achievement. John Gilbert has at least become a real individual whose doings in Australia and even whose intimate thoughts are revealed in his note-books; and if his birthplace, his youth and his life before his association with Gould are probably destined to remain unknown, we are happy that the man, now the curtain has been partly drawn aside, is seen as something bigger than a mere intelligent field collector whose labours made it possible for the wonderful son of a gardener to publish the "Birds of Australia".

But Gilbert's diaries do more than this, for he was foolish enough to become one of the misguided band that placed itself under the leadership of Leichhardt, whose ill-considered overland expedition from "Jimba" (north of Brisbane) to Port Essington (north of Port Darwin) set out in September 1844. During this trying journey, until his death at the hands of the natives on June 28, 1845, John Gilbert, though loyally supporting the leader of the expedition in every possible way, could not refrain from noting, in the intimacy of his diary, the character and the actions of the man who was responsible for the enterprise. These notes made by Gilbert amply confirm those estimates of Leichhardt's character afterwards made by Bunce, Mann and others who were associated with him in his later enterprises. Gilbert's diary throws much light on this unsatisfactory and overrated man, and it is time that the tradition of Leichhardt's greatness be permitted to pass into oblivion.

The real facts concerning Friedrich Wilhelm Ludwig Leichhardt seem to be that, after an obscure boyhood on the farm of his parents in Prussia, he became an unsatisfactory student at Göttingen and Berlin. Infirm of purpose in all things save in a determination to avoid work, he indulged in introspection and became absorbed in overwhelming self-pity. He drifted. It seems certain he never pursued any study to the length of taking a degree. His Australian assumption of the title "Dr." and his claim to be a medical man appear to have been merely indications of vanity, and his treatment of the sick men under his care belies any possibility of a medical training. Unwilling to make any effort to earn his own living, he became parasitic on friends and fixed his tentacles firmly into a worthy English fellow student named William Nicholson. Nicholson brought him to England and later, apparently as the only way of being rid of the incubus, gave him money and paid passage for him to Australia. In his new environment, he again became parasitic on friends and made no effort to find occupation until, financed and equipped at the expense of others, he started on the enterprise for which he had no sort of qualification either of leadership or of attainment. Briefly, he proved disloyal to the men who risked their lives with him, he was callous to the sick men in his charge to the length that he stole their rations when they were no longer able to claim them. He was cruel to animals, on the proper care of which his success so largely depended. Even in a camp of rough men living in rough times and under great disadvantages his personal habits, evinced in his total disregard of hygiene and disgustingly coarse dietetic tastes, proved revolting. These personal characteristics rendered him unfitted to lead; but unfortunately for the men who placed themselves under his leadership, he was devoid of any real knowledge of bush craft and was incapable of taking an accurate observation to determine his whereabouts. On one occasion Gilbert notes that the party had struck a valley which, since they felt sea breezes, they thought would open out into the Gulf of Carpentaria. As a matter of fact, the expedition was not within a thousand miles of the Gulf and the sea breezes came from the east coast near the site of the present town of Rockhampton.

Perhaps a more remarkable circumstance revealed by Gilbert's diary is the fact that within the first four months of the expedition, nine out of the ten members of the party had been hopelessly lost in the bush at some time or other and that the leader had had this unfortunate experience on more than one occasion. To be completely lost in the bush is a terrible experience for any man, but for Leichhardt it was especially dangerous since, as he was unable to use a gun, he was quite incapable of obtaining food. The odd thing is that these experiences never seemed to diminish the man's vanity or to make him any more cautious or responsible; and so Gilbert's story goes on up to the tragic night when he received his fatal spear wound and the diary ceased abruptly.

Even of this incident Leichhardt refrains from telling the truth, which was, however, suspected by Gilbert and told in his diary the day before his death. Leichhardt told the world that the attack of the natives was entirely unprovoked. Gilbert suspected, and Leichhardt knew quite well, that the attack was an act of retaliation by the natives for brutal interference with their women by Brown and Charlie, the aboriginal members of the party.

Here, with the death of Gilbert, we may leave Leichhardt. Had he never undertaken his last ill-conditioned enterprise and with his unfortunate fellows, his circus of horses, mules, cattle, goats, sheep and dogs, vanished completely and for ever, he would probably have been assessed at his true worth and not have become a legendary hero in Australia. As for John Gilbert, all ornithologists are in debt to Chisholm for giving us even a partial picture of a man who, under the worst possible conditions, patiently fulfilled his mission of collecting the

Australian fauna, to the gain of science. Nor was Gilbert a mere collector. It was surely a remarkable thing that, even when short of food, clothing and every other necessity and at the end of a day of hardships, he would sit down and write several thousand words on the habits of birds and beasts observed during the day. To those who have experienced even a minor degree of such conditions it must appear still more remarkable that he wrote all his notes neatly with pen and ink. He had the true spirit of science, and Chisholm is to be thanked for letting us know more about John Gilbert the naturalist as distinct from John Gilbert the man who collected for Gould.

The reviewer has only one regret after reading this valuable addition to our knowledge of birds and men in the early days of Australia. Surely the title—"Strange New World"—is a trivial and even misleading one under which to launch so important a contribution to biography. F. WOOD JONES.

OBITER DICTA OF A SOCIOLOGIST

Diagnosis of Our Time

Wartime Essays of a Sociologist. By Karl Mannheim. (International Library of Sociology and Social Reconstruction.) Pp. xi+179. (London: Kegan Paul and Co., Ltd., 1943.) 10*s.* 6*d.* net.

PROF. MANNHEIM has achieved a position of deserved distinction among sociologists as the author of "Ideology and Utopia". In the present volume he gathers together a number of his addresses delivered to audiences as diverse as the staff members of the University of Durham and the listeners-in of the B.B.C. overseas broadcasts.

In his addresses on education he shows an approach that is in many ways typically Continental and which, in my experience, shows itself whenever the representatives of European universities, secular or Catholic in type, meet representatives of the universities of the English-speaking world. Values are known, Prof. Mannheim feels, and the educator must teach them. In the English-speaking world there is a persistent (and to my mind valuable) prejudice to the effect that truth has to be groped for and that, when 'values are taught' dogmatically, this generally ends by meaning that the schools will teach whatever particular set of values the government and politicians of the day find convenient—whether it be the commandment of the Decalogue "Thou shalt not kill" or conversely the maxim *dulce et decorum est pro patria occidere*. Either way the pure light of disinterested inquiry is smoked.

Prof. Mannheim, however, performs a very valuable service in raising this issue of values, even if his language occasionally seems too guarded and discreet and as if he had the sense of being a guest. Mr. Lewis Mumford and Dr. Archibald MacLeish have raised this issue in the United States and, in a very different but more profound sense, Mr. Herbert Read has done so in Great Britain, as have various theological writers such as Niebuhr and Berdyaev. Prof. Mannheim has my sympathy in endeavouring, unlike the last-named, to state his values in humanistic terms. Like Dr. Peter Drucker he is concerned with what he calls "planning for freedom", and the type of civilization of which he approves, neither National Socialist nor National Communist, fits into this framework. He rightly insists that although we can perhaps teach mathematics, we cannot teach, for example, history, without a sense of social values (which does not mean that it is futile to try to teach history or political science 'objectively'). If this sense is not permitted explicit expression, then, as with the village atheist teaching in the village church school, it finds expression covertly. We have to decide whether we approve of the current worship of 'dynamism' and of what Dr. Mannheim calls "the demoniac image" (by some others called "the heroic image") "of man emphasizing power and the military virtues of discipline", etc. I am frank to say that I myself, holding very strongly views which I imagine are those of Prof. Mannheim, would yet like to see senior schools in which both views—the dynamic-heroic (or demoniac) and the religious-quietist—were taught. I agree with Plato—and I suspect disagree with Prof. Mannheim—in believing that the human race is not monotonous and all cut out of one cloth, but functional—some natural economic Marxists, some natural Fascists or pro-Fascists (such people, for example, as some of our most vocal patriots and contemplatives, bomber-leaders), and some natural or rulers (spiritually or techno-cratically speaking). The real problem of values is to give to each of these attitudes due weight and no more than due weight.

Prof. Mannheim obviously distrusts the Marxist basically economic interpretation of history; is concerned about the excesses of an industrial civilization; touches on that question of neighbour relations now preoccupying the mind of MacMurray, Heard and others under the name of 'community' (incidentally resurrecting the good Prof. Cooley). He assumes, unlike Prof. Laski, "fundamental agreement on the method of experiment" in our democracy. He aspires to develop a philosophy of 'the middle way' between *laisser faire* and totalitarianism. I myself, having sought precisely such a middle way in my "Preface to Action", and found it, as between Germany and the U.S.S.R., as the Anglo-Saxon philosophy of experiment, or what Dr. Fromm calls 'spontaneity', am now inclined to the more pessimistic belief that a rhythm occurs in history between the extremes, and that the only remedy for the extremity of the extreme is to be found in a humanistic scepticism about what can be achieved in the formally political or governmental sphere. What matters are the outlooks of societies rather than the forms of government. What really matters is the conformity of local institutions to the simple human intuitions, and not this plan or that plan as a creed or as more than an empiric instrument to be discarded at convenience. There can be a 'planned freedom' for a steel worker in need of employment and sport; I do not see how there can be a planned freedom, in any profound sense, for an artist of vision. He will have to find his own 'like-minded society'. Freedom, in the last resort, is not a political matter (despite Prof. Mannheim's antithesis of individual and society, meaning society-under-government) but a spiritual matter. However, that what is here called "value standardization" is not only possible in small communities but also can be successful in large is shown by the example of China. I put down this book with the feeling that I should like to see many of its central ideas further developed, and with a desire to be present at a debate between Dr. Mannheim and Dr. Niebuhr. I should be an impartial arbiter.

GEORGE CATLIN.

APPEARANCE OF GLUTATHIONE DURING THE EARLY STAGES OF THE GERMINATION OF SEEDS

By Sir FREDERICK GOWLAND HOPKINS, O.M., F.R.S., and EDWARD JAMES MORGAN

Biochemical Laboratory, Cambridge

TWO interesting papers have been published containing studies of the phenomena with which the present research is concerned. Firket and Comhaire[1] state that while absent in the dry pea, glutathione, or at least –SH compounds, rapidly appear after these are placed under water. These sulphydryl compounds are distributed throughout the cotyledons, seeming to prepare the conditions for the growth of the embryo rather than being produced under its influence. After reaching a maximum they diminish during the growth of the embryo, more slowly when growth proceeds in the dark. Vivario and Lecloux[2] confirm the early appearance of glutathione during hydration. It reaches a maximum after 4–6 hr.; this increase is more rapid at 38°. The authors found that formation is quicker in powdered peas owing to the more rapid uptake of water.

The facts revealed by the above authors are of much interest but the numerical data they present require revision. In each case it was, of course, realized that other reducing substances besides thiol groups might be present. They therefore carried out two titrations with iodine, one with nitroprusside as indicator and the other with starch. The latter gave somewhat higher figures than the former, and the difference was assumed to be due to other reducing substances. It is now known, however, that the use of nitroprusside as an indicator gives unreliable results. Moreover, these results were calculated as glutathione when this was still supposed to be a dipeptide. In any event, although with animal tissues it is usually safe to assume that no other thiol compounds need to be considered, this assumption was not justified in the case of germinating seeds, where protein changes are so active. Free cysteine might well be present, and, indeed, we have found this to be the case.

We have ourselves succeeded in isolating glutathione from germinating peas by methods which will be described.

Experimental

The early appearance of –SH groups during germination is clearly general among plants, and appears universal. On qualitative lines we have proved their presence in the seeds of the following: Gramineæ (endosperm): rye, barley, wheat, maize; Leguminosæ (cotyledons): sanfoin, vetch; Cruciferæ (cotyledons): cabbage, mustard, wallflower; Chenopodiaceæ (endosperm): spinach; Caryophyllaceæ (perisperm): silene.

In each case, 5 gm. was extracted with trichloroacetic acid, the extract saturated with ammonium sulphate and centrifuged, and to the solution one drop of 5 per cent nitroprusside and then ammonia were added. This was usually on about the second or third day of germination. A positive reaction was always obtained varying somewhat in intensity, the strongest being in the Leguminosæ and the weakest in the Gramineæ. Kozlowski[3] obtained qualitative reactions for –SH in a variety of seeds. He also found that the Leguminosæ gave the strongest reaction.

Isolation of Glutathione. We found greater difficulty in this task than is offered in the case of yeast and animal tissues. Our first attempts, however, were made on lines that have been customary, but these early experiences may be very briefly described. We worked chiefly with different strains of the garden pea, and we used trichloroacetic acid as an extractive. Such extracts have the fundamental fault that, in them, all metallic precipitants produce precipitates which are apt to be colloidal in character. We tried cadmium acetate but found that this gave so bulky a precipitate that it could have little selective value. We therefore used the familiar mercuric sulphate reagent. Its precipitates tend to be colloidal, but with careful adjustment of pH we found we could centrifuge and wash them, though at each stage with some loss.

In one experiment 3 kgm. of peas, on the fifth day of germination, was ground up in trichloroacetic acid by use of sand in a mechanical pestle and mortar. In the extract, after some preliminary treatment, we used mercuric sulphate as a fractional precipitant, and from the three fractions, after the usual treatment, we obtained three separate products. Of these only one (the most soluble) yielded the typical copper compound of glutathione on adding cuprous oxide to its solution in 0·5 N sulphuric acid. The product obtained from this acted characteristically as a coagent to glyoxalase activity. Moreover, when heated in aqueous solution, it gave, after evaporation on the open water bath, typical crystals of the diketopiperazine of cysteinyl-glycine. The product evidently contained a large proportion of glutathione, but its melting point was low, and it gave analytical data which showed it to be impure. It is noteworthy that the other two of the three products referred to, after oxidation, showed typical hexagonal crystals of cystine.

Trichloroacetic acid is clearly not very satisfactory for the extraction of plant tissues. Moreover, at this time it became difficult for us to work on a large scale. We therefore worked out another process applicable to relatively small quantities of material; this gave satisfactory results. The seeds are first ground up by hand in a mortar with 0·1 N sulphuric acid and a little washed sand, the extract centrifuged and the solution half saturated with solid ammonium sulphate. The filtrate from the precipitate thus produced (350 ml.) is brought to 0·5 N sulphuric acid. To this, cuprous oxide is added in small quantities with frequent stirring. It is remarkable that no precipitate appears at once, but after standing for twenty-four hours a quite typical precipitate of the copper compound separates. It would seem that some unstable association between the cuprous compound and the ammonium sulphate is first formed (? a co-ordination compound) which slowly decomposes. These facts apply no less to pure glutathione.

The only drawback to this simple procedure is that, owing to the delay in the separation, it is difficult to estimate with exactness the amount of cuprous oxide which is necessary. Slight excess is added, and after standing for twenty-four hours in an open beaker, the precipitate, which may be mixed with a small amount of copper oxide, is centrifuged off and the fluid allowed to stand for a further twenty-four hours. If more of the copper compound separates, this is centrifuged off and added to the first precipitate. After forty-eight hours no further precipitate has ever been observed.

Preparations 1 and 1a. 10 gm. of peas was soaked for twenty-four hours in water and then treated as above. The crystalline copper precipitate, after washing free from sulphate, was decomposed as usual, and the filtrate from the sulphide freed from hydrogen sulphide by a stream of hydrogen. One half was evaporated to dryness in a vacuum desiccator and weighed 25·5 mgm. (51·0 mgm. per cent). This residue titrated with 0·01 *N* iodine used 7·3 ml., equal to 22·41 mgm. (44·82 mgm. per cent) of glutathione. A quantitative estimation was made by Woodward's manometric method[4]. For the latter a four-point reference curve was first obtained to establish accurate relations between the tripeptide and the carbon dioxide measured. The glyoxalase was made from rats' red corpuscles on the lines described by Jowett and Quastel[5]. The amount of the solution used for the estimation contained 0·127 mgm. of the preparation, and the amount of carbon dioxide evolved in 20 min. (99·54 μl.) was equivalent to 23·0 mgm. (46·0 mgm. per cent) of glutathione. As in this experiment the whole solution was taken directly to dryness and not crystallized out from a mother liquor, it will be understood that the slight excess in the weight of the residue might be due to a trace of impurity. But it would seem that the product was practically pure.

100 gm. of the peas, after soaking for twenty-four hours in water, was transferred to a funnel (which permits of an adequate oxygen supply) and allowed to germinate for three days. The peas were then treated as above. The total residue of the final product was 14·6 mgm. per cent, by iodine 11·05 mgm. per cent, and by Woodward's method 11·0 mgm. per cent. These results confirm the statements of Firket and Comhaire[1], also those of Vivario and Lecloux[2], that the sulphydryl groups diminish once actual growth is established.

Preparation 2. The preparation obtained in the last experiment, although giving satisfactory evidence for approximate purity, was not crystalline. We therefore decided to work on a larger scale in order to obtain a crystalline product. We still found it convenient to work on small quantities of 100 gm. each, accumulating the copper compound from eleven such extractions. This, washed free from sulphate and decomposed in the usual manner, yielded 0·346 gm. of a crystalline product. This was undoubtedly pure glutathione. On rapid heating it melted sharply at 190°, and the product mixed with pure glutathione also melted at 190°. It gave the following analytical results, the mean of two closely agreeing duplicates: found C, 39·03; H, 5·52; N, 13·68; S, 10·36; glutathione, $C_{10}H_{17}O_6N_3S$, requires C, 39·09; H, 5·54; N, 13·68; S, 10·42.

Kozlowski[3] was the first to attempt the isolation of glutathione from peas. So far back as 1926, working in the Biochemical Laboratory at Cambridge, he spent much labour on the problem, employing as much as 25 kgm. of material for each extraction. He succeeded in proving the presence of non-protein cysteine but obtained no product identical with glutathione. After Hopkins[6] had described the use of cuprous oxide as a precipitant, he returned to the problem[7], but again was not successful in isolating a pure substance.

It will be remembered that Vivario and Lecloux[2] found that the production of –SH groups proceeded in powdered peas when this material was placed under water. We have confirmed and extended this observation.

Thunberg vacuum tubes were employed. Two series of –SH determinations were made. In one the powder had stood under an aqueous buffered solution; in the second it had stood under a similar solution to which the disulphide form of glutathione had been added. The following are the details of our procedure.

5 gm. of the pea powder was weighed into each of a series of large Thunberg tubes. 16 ml. of water and 2 ml. of *M*/5 Sørensen's phosphate buffer *p*H 6·0 were then added to each tube; to one series of tubes, 2 ml. of water, and to the others, 2 ml. of a solution of the disulphide form of glutathione containing 60 mgm. (neutralized to *p*H 6·0) were then added. The tubes were then evacuated, refilled with nitrogen and again evacuated; the procedure being repeated three times. The tubes were allowed to stand, with an occasional shake, at the room temperature of 17°. At intervals the reaction was stopped by sucking in through the side tube 10 ml. of acid (8 per cent trichloroacetic and 2 per cent metaphosphoric acids) as used by Musulin and King[8]. The precipitate was centrifuged off, successively washed with 5 per cent acid and made up to 100 ml. Half was titrated with 0·01 *N* iodine in the presence of potassium iodide, and the other half with Tillman's reagent using the micro method of Birch *et al.*[9] The iodine value of the very small amount of ascorbic acid as determined by the indophenol titration found under the conditions of our experiment at 18 hr. and 24 hr. has been deducted in the following table.

Hours	0·01 *N* iodine per 5 gm. peas (ml.)		Calculated for glutathione (mgm./100 gm. peas)	
	No GSSG*	+ GSSG	No GSSG	+ GSSG
0	1·4	—	85·96	—
4	2·0	6·2	122·80	380·68
12	2·0	7·6	122·80	466·64
18	2·0	8·8	122·80	540·32
24	2·3	9·1	141·12	558·74
24†	1·5	1·5	92·10	92·10

* GSSG = Disulphide form of glutathione.
† Heated for 15 min. at 70°.

To judge from many known cases, the production of sulphydryl groups is likely to depend on the transference of hydrogen from donators to acceptors capable of yielding –SH groups. In the present case these are likely to be the oxidized form of glutathione together with cystine. We do not yet know whether the former is present ready formed in the seed stores, or whether it may be synthesized rapidly when the necessary amino-acids are made available by proteolysis.

Thunberg, in a number of papers, has shown that dehydrogenases of various kinds are present in seeds, but we do not yet know which of these, if any, are concerned with the –SH production.

Our experiments with the powdered material show that the –SH groups are rapidly formed. Referring first to the preparations containing none of the disulphide form of glutathione, it will be seen from the above table that at the fourth hour their concentration has already reached a maximum.

It will be seen from the table that there was a considerable concentration of the –SH groups present in the pea powder we used for the experiment. This experiment was made at a time of the year when natural germination would occur. There is no doubt that when the atmosphere is warm and moist, reactions may begin in the intact pea.

We were led to try the effect of adding the oxidized tripeptide owing to a suspicion that the hydrogen acceptor groups were saturated before the hydrogen supply was exhausted. It will be seen that, in consequence of this addition, a large increase in the titratable –SH groups was found.

In order to convey an idea of the extent of the reactions, we have converted the whole of the iodine values as though due to the reduction of the disulphide form of glutathione. It will be seen that the powder by itself reaches the relatively high figure of more than 140 mgm. per 100 gm., while with the addition of the disulphide form of glutathione it becomes no less than 540 mgm.

There is no doubt that the –SH groups start disappearing as soon as visible growth begins (see preparations 1 and 1*a*). We have made no attempt to ascertain the nature of their fate.

Summary

(1) When dry seeds are exposed to water, their contents come to display a high concentration of thiol groups, which rapidly reach a maximum. Later, when growth proceeds, there is a steady fall in the concentration of these groups.

(2) A method is described which has enabled us to isolate (from peas) pure crystalline glutathione.

(3) We have also worked with peas in the powdered form, and have found the same rapid production of thiol groups. The powder further displays a high reducing power towards the oxidized form of glutathione.

PRINCIPLES OF THE USE OF NON-REFLECTING FILMS IN OPTICAL INSTRUMENTS*

By DR. K. M. GREENLAND

British Scientific Instrument Research Association

WHEN light from an object passes through an optical system to form an image, a small fraction is reflected at each air-glass surface instead of being transmitted. For normal incidence, the reflectivity is usually between 4 and 7 per cent, depending on the refractive index of the glass. This affects the image in three ways. First, the brightness of the image is reduced. Secondly, the reflected light, eventually reaching the image plane after two or more reflexions at the lens surfaces, invades the dark parts of the image and gives rise to a haze called 'veiling glare'. This reduces the contrast in the image. Thirdly, the reflected light may concentrate near the image plane to form 'glare spots' and 'ghost images'.

Optical systems are therefore only able to function at their best when unwanted surface reflexions are reduced to a minimum, and that is the purpose of non-reflecting films. The property of light on which they depend is that of interference, by means of which the distribution of the radiation is altered in such a way that the reflexion is reduced and the transmitted light increased. Nothing is sacrificed in reducing the reflexion.

Interference at a glass surface is brought about by coating it with a thin transparent film. As we are concerned with getting a reduction of reflected light, it is necessary, as will be shown later, that the film shall be of lower refractive index than the glass. Suppose, then, that a pencil of monochromatic light from a distant point source falls on a glass surface which has been coated with such a film (see diagram).

Consider the composition of the reflected ray *R*. As will be seen from the diagram, it consists of the reflected portion of the ray *A*, augmented by contributions from other rays such as *B* and *C* which emerge at *A′* in the direction *A′R* after multiple reflexions within the film. Similarly, the reflected fraction of the multiple reflexions arriving at *A′* is added to the directly transmitted ray *AT*. The directly transmitted components of *B*, *C*, etc., and their reflexions at the first surface each become part of separate interference systems identical with the one being considered, so that whatever happens to the rays *R* and *T* applies equally to similar rays from any other point on the film.

The calculation of the intensity of the transmitted and reflected beams is tedious and is to be found in the text-books. As an introduction, however, a simplified calculation of the thickness and refractive index of a film giving no reflexion can be made by taking into account only the incident rays *A* and *B*. This is permissible because although a large number of incident rays contribute to the reflexion *R*, the amplitude of their contributions is very much attenuated by the multiple reflexions which they undergo before reaching *A′*.

The composite reflected ray *R* will have zero intensity when the components from *A* and *B* are in opposite phase and equal in amplitude. For the first condition, the optical path difference must be an odd number of half wave-lengths. For a film of thickness t and refractive index μ, the path difference is $2\mu t \cos r$, where r is the angle of refraction at the air-film boundary.

Therefore for minimum reflexion of light of wave-length λ

$$2\mu t \cos r = (2n+1)\,\frac{\lambda}{2},$$

n being an integer, whence

$$\mu t = (2n+1)\,.\,\frac{\lambda}{4}\,.\,\frac{1}{\cos r} \quad . \quad . \quad . \quad . \quad . \quad (1)$$

The condition of equality of amplitudes is met by equating the Fresnel formulæ (which hold for normal incidence and are almost correct for angles of incidence up to 20°) for the amplitudes of the rays reflected at the air-film and film-glass surfaces (refractive index of the glass, μ_g).

$$\frac{\mu - 1}{\mu + 1} = \frac{\mu_g - \mu}{\mu_g + \mu},$$

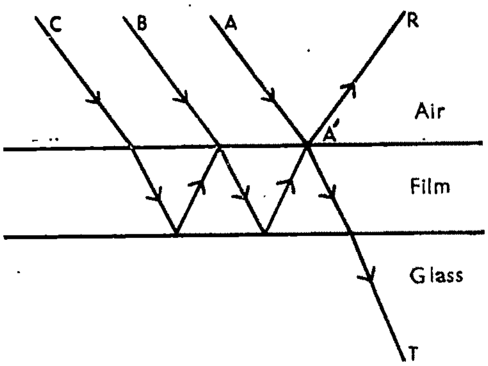
which gives

$$\mu = \sqrt{\mu_g} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

It is not possible to calculate the exact effect on the transmitted beam of a film defined by equations (1) and (2) without taking into account all the multiple reflexions. It is clear, however, that with

---

* Substance of a lecture delivered before the Optical Group of the Physical Society on May 15, 1942.



such a film the fraction of the ray B which after internal reflexions is eventually superimposed on the ray AT must be phase with it, because in addition to the half-wave phase change introduced by the thickness of the film, the two reflexions of the ray from B are of different kinds, one being on the less dense side and the other on the more dense side of the reflecting boundary, which increases the equivalent path difference to one wave-length. The criteria for zero reflectance therefore also provide for increased transmission.

When all the multiple reflexions are taken into account the fraction of the incident intensity reflected from a film of which the refractive index obeys the condition of equation (2) is, for small angles of incidence,

$$\frac{4R\cos^2\frac{1}{2}\delta}{1+2R\cos\delta+R^2}, \quad . \quad . \quad . \quad (3)$$

where R is the reflectivity of the film material under the particular conditions of illumination and δ is $\frac{2\pi}{\lambda}\,2\mu t\cos r$.

The fraction transmitted is

$$\frac{(1-R)^2}{1+2R\cos\delta+R^2} \quad . \quad . \quad . \quad (4)$$

Now according to (3), the reflexion is zero when $\delta=(2n+1)\pi$. Putting δ in terms of path difference as given above, we obtain the optical thickness for zero reflectivity :

$$\mu t = (2n+1)\cdot\frac{\lambda}{4}\cdot\frac{1}{\cos r}.$$

This is the same result as that given by the simplified calculation, because the energy subtracted from the B contribution by internal reflexion at A', which was disregarded, is made up by the contributions through multiple reflexion from all the other incident rays.

When the condition $\delta=(2n+1)\pi$ is applied to the expression (4), we arrive at the interesting result that the transmitted fraction is unity, so that *all* the incident light is transmitted when the reflexion is annulled.

It is most important to realize that the rays do not in fact have to be reflected out into the air before they can annul each other. This is not the kind of interference system where the reflected rays have to be combined by a lens. The interference takes place at the interfaces, and the vectors at a point such as A' are such that there is no resultant intensity in the direction $A'R$. There seems to be a certain reluctance to accept the fact that a non-reflecting film can theoretically increase transmission to 100 per cent. I believe that this is largely due to attempts to explain the phenomenon without taking into account the multiple reflexions.

A film defined in refractive index and thickness by the equations (2) and (3) may be termed the 'ideal' film. Let us now discover, first, how the ideal film behaves under practical conditions of illumination and, secondly, how near an approach to the ideal film can be made with available materials and methods.

The angle of incidence enters into the expression for the transmitted or reflected intensities as a cosine function. This means that if a film is non-reflecting for normal incidence, it will be practically so for angles of incidence up to at least 20°. Within this limit such a film is therefore effective with a broad source, in convergent or divergent beams and on curved surfaces.

By adjusting the thickness of an 'ideal' film, extinction of reflexion could be obtained for any chosen angle of incidence up to about 45°. Above that angle, the condition (2) for the refractive index of the film no longer provides a correct balance of the intensities of reflexion at the two film boundaries. Curves showing the variation of reflectivity with these various factors have been published by Blodgett[1] in a very useful article on the properties of non-reflecting films.

Suppose a film thickness is chosen which gives zero reflexion for a monochromatic green light. If the colour of the light is then changed towards either the violet or the red, some will be reflected, the intensity of reflexion increasing as the wave-length moves away from the green until a maximum is reached. The reflectivity then decreases again as the wave-length approaches that which gives the next higher or lower order of interference. (The wave-lengths for zero reflexion due to successive orders of interference are obtained from equation (1) by putting $n=0, 1, 2, \ldots$). If, then, white light is incident on a film which is non-reflective for a monochromatic green, there will still be no reflexion and maximum transmission of a wave-length in the green, but there will be a number of other maxima and minima within the spectral range, depending on the thickness of the film. If the film is thick compared with the wave-length of the light, there will be so many that the resulting reflexion will also be white, but with an intensity half that of the reflexion from unfilmed glass.

Now it so happens that if the optical thickness of the film is only *one* quarter wave-length of green light (for example, $\lambda=5500$ A.), the nearest maxima are so far away ($\lambda=\infty$ and $\lambda=2750$ A.) that the reflectivity for the red and violet is not more than 1 per cent. The filmed surface then reflects a faint purple colour. (When viewed by eye, the increase of reflectivity towards the ends of the spectrum is offset by the decrease in sensitivity of the eye.) The transmitted light is correspondingly increased but the slight excess of green light does not give perceptible colouring when only one or two surfaces are involved. The 'first order' minimum ($n=0$) is therefore chosen for minimum reflexion over the broadest possible range of wave-lengths. The colour region of maximum transmission and minimum reflexion can, of course, be selected at will by choosing the appropriate film thickness.

Estimation of the thickness of a non-reflecting film is a very simple matter because the colour of the reflexion of white light is a sufficiently accurate measure. All the commonly used methods make the films by building up the thickness progressively, so that as the film thickens the wave-length of first-order interference moves up through the ultra-violet and the violet. The reflected light therefore first diminishes in brilliance and turns yellow. As the wave-length of zero reflexion moves through the visible spectrum, the reflected light becomes orange, magenta, purple, blue, green and, when the minimum is in the near infra-red, greenish-white. The succession of colours is repeated with variations in intensity for successive orders of interference. The most useful colour, purple, denoting maximum transmission in the yellow-green, is a very sensitive indicator.

The refractive index of the film should be the square root of that of the glass. The effect of departing slightly from this condition is not serious: visually it results in a 'whitening' of the coloured reflexion because there will be a small residual reflexion at the wave-length of minimum reflectivity. (A 'purple' film of refractive index 1·35 on plate-glass would have a reflectivity in the yellow-green of about 0·6 per cent.) No attempt is made in practice to match the refractive index of films to every type of glass. Instead, a material is chosen which is reasonably well suited optically to a range of refractive indexes and has at the same time good mechanical properties. Silica, sodium aluminium fluoride (cryolite), and magnesium fluoride are commonly used.

A silica film has the great advantage that it is made of the substance of the glass itself, so that it is inherently a durable film. The film is formed by dissolving away the other constituents of the glass in such a way that the silica skeleton remains undisturbed and the polish of the surface is preserved. With glasses such as dense barium crowns and dense flints, the film can be formed naturally by the weathering action of the atmosphere. This 'tarnish' was first reproduced artificially by H. D. Taylor[2] in 1892, and the details of the chemical method are now well established[3]. Owing to the high refractive index of the silica film, even in its skeletonized state, it is only really effective on very dense glasses. Lately Nicoll[4] has described a new chemical method in which hydrofluoric acid vapour is the dissolving agent; good results are claimed with glasses of medium refractive index.

The fluoride films are deposited by the high-vacuum volatilization process[5], the technique being very similar to that used for making metal-on-glass mirrors. The powdered fluoride is evaporated by heating it electrically in a vacuum; it condenses in a vitreous film on any relatively cool surface directly exposed to the source. The surfaces to be coated are so placed that the condensed film is perfectly uniform in thickness. The vacuum is maintained by a fast mercury or oil diffusion pump at a pressure of not more than 10^{-4} mm. of mercury; by using very efficient pumps and taking great care to prevent leaks and evolution of gas in the vacuum chamber, the number of gas molecules can be reduced to as few as one million million per c.c.

The volatilization method generally gives a film of greater optical efficiency than does the chemical method. Magnesium fluoride forms very hard films and is a good match for the denser glasses, while cryolite is a good compromise for the whole range of optical glasses and can be made quite hard enough to withstand unavoidable handling.

In practice, it is found that a reflectivity in white light of not more than 1½ per cent may be expected and that a smaller loss than that is often achieved. Some striking results in the reduction of glare have been reported[6]. Published results for which the conditions of measurement are not given should be accepted with caution. The measurements are sometimes made with monochromatic light, which may give a more favourable result than those made with white light. It even happens that the results are not obtained by measurement but merely calculated on the basis of a reflectivity of, say, 0·4 per cent per surface, and without taking into account the absorption of the glass.

It is hoped that this survey has shown that the optical principles of non-reflecting films permit them to be used under everyday conditions. They are not merely scientific curiosities but are capable of bringing about a very real improvement in the performance of optical instruments.

PERMEABILITY AND MOLECULAR CONSTITUTION AS FACTORS IN DRUG ACTION

By DR. H. HURST

Department of Colloid Science, Cambridge
and Imperial College of Science and Technology, London

ONE of the chief difficulties in the interpretation of the analogies between the biological activity of a drug and its behaviour in synthetic systems arises from the ambiguity of toxicological data, which may generally be correlated with solubility in the cell lipoids (Overton-Meyer), adsorption at cell interfaces (Traube), or with other physico-chemical factors. Moreover, these analogies may not hold when other biological systems and homologous series of drugs are compared. Recent work on molecular interaction in monolayers has provided a very valuable guide to the factors which influence specific drug reactivity in pharmacological systems[1]. The principles which have been advanced have greatly extended the implications of the original conceptions of Overton-Meyer and Traube.

In the present article, an attempt is made to correlate existing pharmacological data and theories of drug action with experimental evidence which has resulted largely from a study of the mode of action of insecticides. This work, which was commenced some years ago in Prof. J. W. Munro's Department of Zoology and Applied Entomology at the Imperial College of Science and Technology, London, is at present being extended in the Department of Colloid Science, Cambridge.

Insects comprise a very wide range of biological systems which show a similarly wide range in susceptibility to different drugs. For example, mature blowfly larvæ (*Phormia terrænovæ*) are resistant to high concentrations of drugs applied externally. The iso-active concentrations of alcohols and fatty acids which produce rapid paralysis or narcosis when injected internally into the hæmolymph are relatively inactive over prolonged periods when applied externally, showing that cuticle permeability may be a limiting factor in drug reactivity.

If a comparison is made between the relative external and internal biological activities of members of the homologous series of normal primary alcohols and fatty acids, a wide divergence is shown between corresponding homologues in both series. When Phormia larvæ are immersed in pure drugs, the rate of penetration of alcohols through the cuticle increases as the series is ascended from C_1 to C_5, when maximum biological activity is shown; from C_5 to C_8 there is a progressive decrease in biological activity. Under similar conditions of drug application, the rate of penetration of fatty acids decreases as the series is ascended from C_1 to C_5; from C_5 to C_7 there is a progressive increase in the rate of drug access (C_8 in the fatty acid series is solid at normal room temperatures, and is not suitable for comparison with the liquid drug members).

These results show clearly that drug access cannot be correlated directly with distribution in a heterogeneous system of immiscible phases comprising the external drug phase and the various biophases of the test insect. In homologous series, physical properties such as differential oil/water solubility, capillary activity, viscosity, or vapour pressure change uniformly in the *same directions* as drug chain-length increases. Neither can the divergence between the rates of drug access of corresponding homologues in both series be attributed to differences in concentration gradient across the bulk cuticle framework. The total decrease in molar concentration of pure drug is roughly fourfold as each series is ascended from C_1 to C_8; the absolute molar concentrations of corresponding members of both series are approximately equal.

Still further complications arise when a comparison is made between the relative threshold iso-active molar drug concentrations which produce paralysis when injected into the hæmolymph. The molecular activity of the alcohols increases as the series is ascended from C_1 to C_5, and the relation between biological activity and chain-length approximates to a typical exponential form which is characteristic of toxicological data expressing equilibria between drugs and biological systems. In the fatty acid series, the *iso-active molar drug concentrations remain relatively constant* as the series is ascended from C_1 to C_8. The molecular activity of formic acid is roughly 70–80 times that of methyl alcohol. In both series the intensity of paralysis or narcosis diminishes when the chain length exceeds C_5.

If the comparison between external and internal molecular drug activity is extended to the related series of blowfly larvæ (*a*) *Calliphora erythrocephala*, (*b*) *Phormia terrænovæ*, (*c*) *Sarcophaga falculata*, it is found that relative resistance to drugs applied externally increases in the order (*a*) → (*b*) → (*c*). When the drugs are applied internally by injection, iso-activity is shown by threshold narcotic drug concentrations in all three species of test insect.

This experimental evidence leads to the important conclusion that where diffusion through an intermediary biophase which links the site of drug application with the site of drug interaction is a limiting factor in drug access, relative biological activity measured at the site of drug application may differ from relative activity at the site of action. Drug reactivity may increase, decrease, or remain relatively constant as a homologous series is ascended, according to the mode and site of application.

If we attempt to elucidate the mechanism of drug access through the insect cuticle, it is first necessary to define clearly the nature of the drug interaction with the cuticle framework, which consists of a heterogeneous system of protein, lipoid, chitin, and other components[2]. The nature and relative distribution of these components vary considerably in different insects, but the fundamental cuticle *pattern* may be illustrated by some experiments which have been carried out on the cuticle of blowfly larvæ (for example, *Calliphora erythrocephala*).

Proteins and lipoid substances may be removed from the surface of the blowfly cuticle by the solvent or dispersant actions of water and fat solvents respectively, suggesting that the surface of the cuticle is not homogeneous but composite, consisting of heterogeneous protein and lipoid associations or patches. Similar tests with discrete layers of isolated cuticle indicate that there is a *continuity* of lipoid and protein components throughout the bulk cuticle framework. From this evidence, we may conclude that *functionally* the insect cuticle is analogous to a heterogeneous mosaic system comprising a protein phase associated with a hydrophobic lipoid phase.

An indication of the physical nature of the lipoid components of the cuticle is provided by a comparison of the 'carrier action' of different fat solvents. The primary association of fat solvents with the cuticle framework is physical, and the changes in permeability which are induced are readily reversible. For example, Calliphora larvæ, which are very resistant to pure ethyl alcohol, swell rapidly in ethyl alcohol-kerosene mixtures owing to induced penetration of alcohol by the functional participation of kerosene in the cuticle framework[3]. Penetration of alcohol ceases, however, when the insects are transferred to pure alcohol owing to 'wash-out' of the kerosene from the cuticle framework. After prolonged preliminary immersion in fat solvents, an irreversible increase in cuticle permeability takes place. This is shown by the rapid penetration of pure drugs such as methyl or ethyl alcohol. The rate of drug access is still further increased by fat solvents, showing that only a proportion of the lipoid components is dispersed or removed from the cuticle by fat solvent action. These experiments show that drug access cannot be explained by differential solubility in the lipoids of the cuticle, for if this were a limiting factor, removal of lipoid would tend to diminish drug access.

The physical nature of the oil carrier has a marked influence on the degree of induced drug penetration. Increase in carrier viscosity results in a corresponding decrease in drug access. If it is assumed that the oil carrier acts as a kind of 'diluent' in the lipoid centres, resulting in an increase in free volume of this phase, the variation in drug access with carrier viscosity may be explained by postulating a lipoid phase which is normally of high 'functional viscosity'. The term 'functional viscosity' is not strictly comparable with Newtonian viscosity in a homogeneous liquid, since the protein and lipoid components of the insect cuticle are heterogeneous visco-elastic systems comprising chemically linked networks enclosing the more mobile or labile components which may be removed by solvent action. 'Functional viscosity' gives a measure of the 'yield value' of the lipoid phase to drug diffusion pressure.

From these considerations, the increase in cuticle permeability which is produced by the association of fat solvents with the cuticle framework may be attributed to:

(*a*) A van der Waals' interaction between the fat solvent molecules and the lipoid centres, involving a reduction in mutual cohesion between the lipophilic elements or chains, and resulting in the production of a relatively open three-dimensional chemically linked network enclosing the more labile or liquid lipoid components in which the fat solvent molecules are present. In this way the fat solvent increases the free volume of the bulk lipoid phase, and may also act as a 'bridging' medium which links discrete lipophilic patches in the bulk cuticle phase. Since both protein and lipoid components are enclosed in an elastic lattice framework, alterations in the lipoid phase probably induce associated changes in molecular orientation in the protein phase. Fat solvent 'carrier activity' decreases with increase in viscosity, suggesting that the bulk lipoid phase is normally of high 'functional viscosity'. The main site of 'carrier activity' is in the outer epicuticle layer where lipoid components predominate.

(*b*) A secondary irreversible increase in the flexibility of the lipophilic lattice elements owing to rupture of the van der Waals' bonds which normally influence the stability and elasticity of the lipophilic chains. The elastic restoring forces of the lattice framework oppose the dispersive or disruptive action of the fat solvent. The irreversible increase in permeability is due to the removal of the labile 'bonding' components by fat solvent action, and also to a decrease in 'functional viscosity' of the bulk phase resulting from dispersive action of the fat solvent.

Additional evidence which supports the conclusion that the labile cuticle components act as a 'bonding' phase which regulates the cohesion of the chemically linked cuticle lattice elements is provided by the mode of action of insecticidal powders or dusts. Finely divided 'inert' powders such as quartz or charcoal readily adsorb the relatively labile lipoid or lipo-protein components from the surface of the epicuticle. This process is non-specific, and depends on the adsorptive and storage capacities of the powder, and also on the capacity for lipoid transmission at the epicuticle/powder interface. When the rate of removal of lipoid by adsorption displacement exceeds its rate of replenishment by transmission through the bulk cuticle phase, irreversible secondary changes are produced in the epicuticle framework. Depletion of the labile 'bonding' phase results in a reduction in lateral cohesion of the lattice elements owing to rupture or dispersion of cross-linkages. Once this stage is reached, the insect is unable to control the rate of transmission of water through the cuticle even when the external powder phase is removed, and rapid water loss soon results in death from desiccation. In the normal insect, variation in the rate of secretion of the 'bonding' phase by the epidermal cells may result in corresponding changes in free volume and 'functional viscosity' of the lipophilic centres in the epicuticle framework, thus providing a very sensitive regulatory mechanism for the control of water loss. Analogous effects, which have been obtained in synthetic systems, have provided a very useful basis for predicting the toxicity of insecticidal dusts.

Extending the above concepts of carrier action, we see that a drug may either induce its own penetration, or exert a carrier action similar to that of a fat solvent, provided that the dispersive van der Waals' interaction with the lipoid components is sufficiently strong. For example, access of ethyl alcohol may be induced by octyl alcohol. In the homologous series of alcohols, 'carrier activity' increases to a maximum and then decreases as the series is ascended and capillary activity becomes pronounced. In fact, strongly capillary active alcohols such as cetyl alcohol exert 'negative carrier activity', or antagonism, on the rate of access of a lower homologue such as amyl alcohol. In the fatty acid series, 'carrier activity' becomes pronounced at a later stage (C_6–C_7) than in the alcohol series (C_4–C_5).

This change in 'carrier activity' with capillary activity has a very direct bearing on the mechanism of drug access, for it suggests that a two-dimensional diffusion takes place along the internal lipoid/protein interfaces of the bulk cuticle framework. Within the range C_1–C_8 the adhesion between the hydrocarbon chains of the drug molecules in the series of alcohols and fatty acids is small, and the adsorbed molecules form mobile 'gaseous' surface films[4]. Drug access will depend on (*a*) the association of the polar portions of the drug molecules with the aqueous protein phase, (*b*) the van der Waals' association between the hydrocarbon chains of the drug molecules and the lipoid phase, and (*c*) the interfacial viscosity at the Gibbs' layer.

Two-dimensional drug diffusion along the Gibbs' layer does not preclude three-dimensional diffusion through the bulk lipoid and protein phases of the cuticle, but with this definition of the drug-cuticle phase distribution relations it becomes possible to co-ordinate the gross divergence in drug access between alcohols and fatty acids which was recorded earlier in the present article.

Weak polar interaction of alcohols with the proteins of the cuticle is insufficient to induce penetration through the protein phase. Similarly, the weak van der Waals' interaction of the lower members (C_1–C_3) with the lipoids results in feeble 'carrier activity' within this range. As the series is ascended from C_1 to C_5, the increase in 'carrier activity' owing to dispersive action of the alcohols on the lipoids results in a progressive increase in cuticle permeability. A specificity factor appears to be involved in the non-polar association of the drug molecules with the lipoids of the cuticle, for dispersive action decreases as the series is ascended further from C_5 to C_8, in which range drug access also decreases. The ambiguity between the 'rival' theories of drug reactivity which were mentioned at the beginning of this article, disappears when we consider the physico-chemical factors which influence penetration of amyl alcohol through the cuticle. The intermediary stages in drug access involve the following steps. (i) Differential solubility in the cuticle lipoids resulting in a decrease in 'functional viscosity' of this phase; this agrees with the Overton-Meyer theory of lipoid solubility. (ii) Adsorption at the lipoid/protein interfaces or Gibbs' layer in the cuticle framework mosaic; this is in accordance with the Traube concept of drug adsorption at interfaces. (iii) Molecular interaction with the functional cuticle components at the Gibbs' layer; owing to weak polar interaction with the protein components, there will be little tendency for the drug molecules to become 'anchored' at the Gibbs' layer, and the mobility of amyl alcohol will now depend on the interfacial viscosity. The antagonistic action of carriers of high capillary activity (for example, cetyl alcohol, oleyl alcohol, cholesterol, or oleic acid) on access of drugs of lower capillary activity may be attributed to selective blocking of the Gibbs' layer by the carrier components of the drug mixture. The penetration of lower alcohols (for example, ethyl alcohol) is induced by carriers of moderate capillary activity (for example, octyl alcohol) because the increase in drug mobility owing to dispersive carrier activity is a more important factor than the opposing influence of selective carrier adsorption at the Gibbs' layer. The rapid drug penetration which is induced by non-polar solvents such as kerosene may be attributed to pronounced carrier activity and negligible carrier adsorption at the Gibbs' layer.

The strong polar interaction of fatty acids with the protein components of the cuticle is sufficient to induce selective penetration through the protein phase[5]. Phormia larvæ, which will survive for at least two hours in methyl alcohol, are killed within three or four minutes when immersed in formic acid. We can visualize a kind of competition between the lipoid and protein components of the cuticle for the fatty acid drug molecules. Where chain-length is short (for example, formic acid) polar group interaction will be a limiting factor in drug access. The penetration and expansion of synthetic monomolecular amine and protein films by carboxylic acids suggest that the penetration of a fatty acid through a three-dimensional protein gel involves a preliminary rupture or dispersion of salt interlinkage systems (for example, $-\overset{-}{\mathrm{COO}}\ \overset{+}{\mathrm{NH}}_3-$) owing to competition from the polar groups of the drug molecules. As capillary activity increases, the drug molecules will tend to become anchored at the external layer of the cuticle owing to a balance between the polar and non-polar interaction of the drug molecules with the lipo-protein associations at the Gibbs' layer. The stability of the lipo-protein-drug association reaches a maximum at C_5, when drug access is at a minimum. From C_5 to C_7 this stability decreases as the influence of non-polar interaction begins to predominate over the competing influence of polar interaction. Dispersion of the lipoid phase now becomes a limiting factor in drug access, and this carrier activity accounts for the increase in drug reactivity within this range.

The relative internal drug reactivities may be explained from similar considerations. Within the range C_1–C_5, the logarithmic increase in molecular activity of the alcohols may be attributed mainly to non-polar interaction of the drug molecules with the lipoid loci at the site of action; the relative influence of head group interaction of the 'inert' drug molecules with the protein receptors is negligible. This explains the fact that the relative molecular activities of the alcohols form a typical Traube series. The iso-activity of the fatty acid molecules within the range C_1–C_5 suggests that drug reactivity is influenced mainly by polar interaction with the protein receptors. A factor of non-polar specificity is suggested by the iso-activity of alcohols and fatty acids at a chain-length of C_5; in both series the intensity of narcosis decreases with further increases in chain-length. It is of interest that where the drugs are present as an external phase, a similar factor of non-polar specificity results in a maximum divergence between the relative rates of drug access of corresponding homologues in both series.

The principles which have been proposed in the present article have been based on a very restricted range of pharmacological systems. The fundamental components of a pharmacological system may be resolved into (i) the biological system; (ii) the drug; (iii) the carrier. The ambiguity of existing theories of drug interaction disappears when the relationships of *all* the components in the system are taken into consideration. Failure to recognize the fact that each constituent of a drug mixture may contribute towards gross toxicity imposes a severe restriction on the general application of 'standard' methods of drug bio-assay, especially in connexion with methods which have been proposed for the biological evaluation of insecticides[6]. The general tendency has been directed towards arbitrary elimination of the disturbing influence of unknown variable factors, and 'evaluation' of an insecticidal mixture has been based on the assumption that the main function of a carrier medium is to bring the drug into contact with the biological system, after which drug concentration provides the limiting factor which determines biological activity. The only 'official' test which is at present in use for the evaluation of contact liquid insecticides is the Peet-Grady method[7], in which houseflies are liberated into a specially designed cubical spray chamber and then sprayed with a standard 'dosage' of reference insecticide; comparison is then made with the results of a similar test using an insecticidal mixture of unknown composition. It has generally been assumed also that 'mist action' of the finely atomized spray is mainly responsible for 'knock-down' action. The flaws in these assumptions are shown, by the fact that, under similar conditions of application, a given concentration of contact insecticide (for example, 0·1 per cent pyrethrins) in kerosene produces a rapid 'knock-down' action; a similar concentration of pyrethrins in a heavier oil of the medicinal paraffin type produces a negligible 'knock-down' action, and cannot be 'evaluated', although the mist action is superior to that produced by the lighter oil. This is due to the rapid penetration of pyrethrins which is induced by the kerosene; despite a pronounced mist action, the shortness of the mean life of the atomized heavier oil droplets precludes 'knock-down' action, since carrier activity is relatively slight in comparison with the kerosene spray.

If we extend the principles which have been here elucidated, we see that drug access in an extremely wide range of biological systems may be explained on the assumption that these systems are of the same fundamental *pattern* as insect cuticle. In other words, a visco-elastic lipo-protein mosaic appears to be a common factor in the organization of living biological systems. For example, physico-chemical factors which influence drug access through insect cuticle also apply to drug access through other arthropod integuments, the cuticles of nematode parasites, and various vertebrate pulmonary, muscle, and nerve tissue lining membranes. The analogy may be extended to microscopic systems such as red cells, where the surface is said to consist of a molecular lipo-protein mosaic[8]. Reversible disk-sphere transformations may be produced by primary interaction of fat solvents with the ultra-structure of the red cell. Prolonged interaction disrupts or disperses the lipo-protein associations and results in hæmolysis. The chain of analogies also bridges the gap between animal and plant systems. There is a parallelism between the outer 'cutinized' layer of plant epidermal tissues and insect epicuticle.

If we now consider the drug components, we see that the range of drugs which shows the effects of induced penetration by fat solvents includes feebly dissociating alcohols, ketones, fatty acids, amines, and phenols. The drugs penetrate as unionized molecules. This is in agreement with their greater activity in carriers of low dielectric constant, and also with maximum adsorption at the Gibbs' layer.

The carriers which facilitate drug access include a wide range of aliphatic and aromatic fat solvents. Generally, carrier activity decreases with increase in capillary activity.

Finally, this review of the fundamental analogies between different pharmacological systems may be concluded by stressing the fact that the analogies between liquid drug systems also apply to drugs and drug mixtures in the vapour phase. For example, a mixture of fumigants may be more toxic to insects than the separate components. This may be attributed to the condensation and functional association of the drug components with the cuticle framework.

A full account of the above work will be given elsewhere.

NEWS and VIEWS

Anglo-American Unity and World Peace

ANGLO-AMERICAN unity was the theme of the address delivered by Mr. Churchill when he received the honorary degree of doctor of laws at Harvard University on September 6. American participation in international affairs, Mr. Churchill said, is not only necessary but also inevitable. Twice in a generation the American people have been drawn into a major war, and a new world order is impracticable without their active participation; the "price of greatness is responsibility". Collaboration among the United Nations has now brought us to a point where there can be no pause. "It must be world anarchy or world order." A potent factor in promoting the joint action of Great Britain and the United States has been the Combined Chiefs of Staff Committee, working immediately under President Roosevelt and Mr. Churchill. This body has reached the stage when it ignores distinctions between things American and British, and disposes of troops, equipment, transport and munitions as if they were the resources of a single nation. This powerful and smoothly running system should not be broken up until we are assured of a practicable form of world security. Looking specifically to the future, Mr. Churchill remarked that various schemes for achieving world security while safeguarding national rights and traditions are being studied. Good work was done in this direction by those who devised the League of Nations, which became ineffective because it was abandoned and its best friends infected with pacifism. "We have learned from hard experience that stronger, more efficient, more rigorous world institutions must be created to preserve peace and to forestall the causes of future wars."

The possession by Great Britain and the United States of a common tongue is, Mr. Churchill said, a priceless inheritance which has smoothed the way to collaboration and "may well some day become the foundation of a common citizenship". Indeed, Mr. Churchill looks beyond that to spreading the English language even more widely throughout the world, and he mentioned that he had persuaded the British Cabinet to set up a Committee of Ministers to study and report upon Basic English. No doubt this committee will take account of the discussions on the use of an auxiliary world language being conducted by the British Association Committee on Post-War University Education and by the Association of University Professors and Lecturers of Allied Countries in Great Britain (see NATURE, December 19, 1942, p. 716 and August 21, 1943, p. 221). Harvard, Mr. Churchill said, has done more than any other American university to promote the use of Basic English, through its Commission on English Language Studies, which has introduced the use of Basic English in Latin America, and is working with certain secondary schools on its use in teaching English to American children and to foreigners preparing for American citizenship. With characteristic understatement, Mr. Churchill remarked, "it would certainly be a grand convenience for us all to be able to move freely about the world . . . and to be able to find everywhere a medium, albeit primitive, of intercourse and understanding".

Barricade Against Spread of Rinderpest in Africa

LATE in 1939, there was news of rinderpest in the south of Tanganyika Territory. Brought originally from Asia, the virus of the disease found a new home in the game and cattle countries in the interior of East Africa. Here those animals which recovered from the first attacks had gained some immunity, thereafter acting as reservoirs of the virus. Then during the War of 1914–18 German manœuvres had carried infected oxen right down to Lake Rukwa in southern Tanganyika, and it seemed that this area might now become the source of further spread towards the south. Consultation between all the Governments of East, Central and South Africa achieved certain conclusions, foremost among them being that at all costs the disease must be stopped from crossing the border between Tanganyika Territory and Northern Rhodesia. Mass inoculations created a safe zone in which the rinderpest virus could not maintain a hold among the cattle. There remained the wild game. The problem was to break the contact between the game in Tanganyika Territory and that in Northern Rhodesia and Nyasaland to the east. Nyasaland is well protected naturally by closely settled belts of native population and a broad river running between high hills; but there is little on the Northern Rhodesia border to check the passage of game. It was decided, therefore, to build a fence along the danger line, from the south end of Lake Tanganyika to the Nyasaland border, a distance of more than 160 miles. The fence was started in August 1940. A stockade seven to ten foot high was made of timber near to hand; only through timberless open plains could the very limited supply of wire be used, fifteen miles in all. The whole fence was finished within a year from the start.

Constant vigilance is necessary to keep the fence in daily repair. Elephant on their customary journeys have smashed through the structure time and again; but fortunately elephant do not carry rinderpest. A human cordon ran the length of the fence: pickets of native African guards, patrolling and linking up each day so that nothing could get through without detection; all under two white officers' supervision. At the eastern end of the fence Nyasaland linked up and carried the human cordon down to the shores of Lake Nyasa, thus completing the great barrier between the two lakes. The game in the fence zone is gradually being pushed back on either side, and in time the danger of contact between north and south should pass away. But the fence itself has proved so valuable in controlling the position that attempts are now being made to prolong its life indefinitely by trenching (the best security against wild pigs) and planting thorns and sharp-spiked sisals which will discourage any buffalo or soft-skinned game from approaching even if they do escape the vigilance of the hunters.

New Synthetic Rubber

A NEW specialty rubber known as 'Paracon' has been developed by the Bell Laboratories, which looks and feels like ordinary rubber and resembles it fairly closely in mechanical properties (*Bell Lab. Rec.*, 20, No. 9; May 1943). It has a high resistance to damage by oil or petrol and is better than natural rubber in resistance to heat, light and oxidation, although inferior to it in resistance to steam, alkalis and acids. 'Paracon' can be worked with ordinary rubber machinery. In its raw state it is highly plastic and unusually well adapted to moulding into intricate shapes and to use in producing rubberized fabrics. 'Paracon' does not compete with other synthetic rubbers for its basic raw materials since the chemical intermediates required for its production are derived by other trains of chemical processes. For its synthesis it uses materials derived from agricultural products and coal products, or from coal and petroleum sources, and in each case by a variety of different chemical processes. The equipment for manufacturing 'Paracon' differs from that required for synthetic rubber production and, consequently, the new material can add to the present supply of rubber substitutes without interfering with the production of those already under way. The synthesis of 'Paracon' was accomplished by Drs. C. S. Fuller and B. S. Biggs of the Bell Laboratories and their associates.

Public Health in Peru

THE February issue of the *Boletin de la Oficina Sanataria Panamericana* contains an article on public health in Peru by Dr. Manuel Prado, president of the Republic, who states that during 1941–42 more attention has been given to it by the Government than ever before. Owing to the general census of 1940 much more accurate data have been made available. The birth-rate, for example, is now found to be rising in many of the provincial capitals, while the death-rate remains unchanged in most of the villages. Considerable attention has been given to children. In addition to the Children's Hospital, which receives children not only from Lima but also from neighbouring villages and towns, there is a National Children's Institute which has made possible the creation in various cities of sections of maternal aid, social hygiene, maternal education and food dispensaries. An intense campaign has been carried out against disease, especially tuberculosis and malaria. Clinics for tuberculosis have been established in three cities and others will soon be formed. A portable X-ray apparatus has been provided for rural communities as well as other means for the diagnosis and treatment of this disease. The Rockefeller Foundation is now collaborating with the Peruvian Ministry of Health in an effort to free the valleys of the coast from malaria. Preventive measures are reducing the foci of other diseases, particularly venereal diseases. First-aid services are assuming greater importance not only for minor accidents but also for major catastrophes. The value of sanitary engineering has recently been proved by its control over bathing establishments and markets, and over food, especially milk.

Narcotic Drug Addicts

IN Supplement No. 170 of *Public Health Reports* Dr. Michael J. Pescor, assistant surgeon, United States Public Health Service, records a follow-up study of 4,766 narcotic drug addicts who had been discharged from the United States Public Health Service Hospital at Lexington, Kentucky, during January 1, 1936–December 31, 1940. The results were as follows: The present state could not be determined in 39·6 per cent of the cases; 7·0 per cent died after discharge; 39·9 per cent returned to the use of drugs and 13·5 per cent were still abstinent. Excluding the dead and the unknown, 74·7 per cent had relapsed and 25·3 per cent were still abstinent. 57 per cent of the patients gave no history of subsequent admission to any institution; 19·9 per cent were re-admitted to other institutions, 16·0 per cent returned to the Lexington Hospital only and 7·1 per cent were re-admitted both to the Lexington Hospital and other institutions. According to Pescor the theoretically ideal patient, that is the one with the best prospects for a permanent cure, is the one who stays in the hospital for 2–5 months, after which he is discharged on parole for a period of supervision of 2–5 months, during which he would have home employment.

Poliomyelitis in the Argentine

ACCORDING to the *Journal of the American Medical Association* of February 6, the number of cases of acute poliomyelitis in the Argentine since last November was greater than in previous epidemics and the course of the disease has been similar to that of the 1936 epidemics. About four hundred cases were reported in two months in the epidemic area, in which more than seven hundred cases were observed during the whole epidemic period of five months in 1936. Separate wards and six hundred beds in various hospitals have been reserved for cases of the disease. Good results have recently been reported from the use of tetanus toxin.

Prevention of Blindness

THE Department of Health for Scotland has recently issued a circular containing the following advice to local authorities on the prevention of blindness: (1) A wider use should be made of special schools and classes for children whose eyesight is defective, arrangements being made with neighbouring authorities when necessary. (2) There should be a closer connexion with industrial medical services to ensure that children leaving school and entering industry are not given jobs making heavy demands on defective eyesight. (3) Facilities for expert consultation and treatment of infections responsible for blindness should be increased. (4) Travelling expenses should be defrayed to treatment centres, of both the patient and a companion.

The Faraday Society

THE Faraday Society has arranged a discussion on "Modes of Drug Action", to be held at the Hotel Rembrandt, London, S.W.7, on September 24. There will be morning and afternoon sessions, at which introductory addresses will be given by Prof. J. H. Gaddum and Prof. E. K. Rideal, devoted respectively to biological and physico-chemical aspects of the subject.

Association for Scientific Photography

THE first meeting of the session for 1943–44 of the Association for Scientific Photography will be held on September 18 at the Middlesex Hospital, London, W.1, to discuss papers on clinical photography. Future meetings will be held monthly; the October meeting will deal with the use of photographically sensitized metal, wood and plastics in industry, the November meeting with oscillographic recording, and the December meeting will be devoted to an exhibition of scientific photographic apparatus arranged jointly with the Scientific and Technical Group of the Royal Photographic Society. Further particulars can be obtained from the honorary secretary of the Association, Tavistock House North (1st floor), Tavistock Square, London, W.C.1.

ASLIB Conference

THE ASLIB Conference, 1943, to be held in the rooms of the Royal Society, Burlington House, London, W.1, during September 18–19, has been designed to provide a platform for discussion of some of the outstanding problems of the rehabilitation of special library and information services after the War, chiefly to give a lead to immediate action. The whole of Saturday afternoon has been given to a symposium on rehabilitation and it is hoped that the discussion will bring the British, American and European needs and opportunities into proper relationship. At the inaugural meeting of the Conference, Prof. J. D. Bernal, as a man of science who has always placed a high value on the positive function of information services at the centre of scientific activity, will draw a picture of what must be expected of information services if they are to fulfil this positive function in the scientific life of the post-war world. Further information can be obtained from the Secretary, ASLIB, 31, Museum Street, London, W.C.1.

Miners' Welfare Scholarships and Exhibitions

THE Trustees of the Miners' Welfare National Scholarships and Students' Exhibitions Funds announce the award of nineteen scholarships and nine exhibitions in 1943, as follows:

Scholarships:

Francis D. Davies, of Dinnington, Yorkshire, tenable at the University of Sheffield; Kingsley R. Fox, of Fenay Bridge, Yorkshire, tenable at the University of Leeds; Geoffrey F. Gill, of Barnsley, Yorkshire, tenable at the University of Sheffield; Raymond Hall, of Bakestone Moor, Nottinghamshire, tenable at the University of Sheffield, for honours degree courses in mining; Robert H. Kirkup, of Radcliffe, Northumberland, tenable at King's College, University of Durham, for an honours degree course in electrical engineering; Edward M. Robson, of Monkseaton, Northumberland, tenable at King's College, University of Durham, for an honours degree course in mining; Ernest Blewitt, of Cudworth, Yorkshire, tenable at Selwyn College, University of Cambridge, for an honours degree course in natural science; Ben R. Brown, of Swinton, Yorkshire, tenable at the University of Manchester, for an honours degree course in chemistry; Jeffrey Ellison, of Old Sharlston, Yorkshire, tenable at the University of Leeds, for an honours degree course in colour chemistry; James B. Finean, of Wombwell, Yorkshire, tenable at the University of Birmingham, for an honours degree course in chemistry; Thomas G. Griffiths, of Cilfrew, Glamorganshire, tenable at Queen's College, University of Oxford, for an honours degree course in modern languages; Jean Haswell, of Clipstone, Nottinghamshire, tenable at the University of Reading, for an honours degree course in English; Joseph Hutchinson, of Kimblesworth, Co. Durham, tenable at King's College, University of Durham, for a degree course in dental surgery; Harry O. Morton, of Balby, Yorkshire, tenable at King's College, University of Cambridge, for an honours degree course in natural science; Thomas A. I. Tees, of Twyn, Carmarthenshire, tenable at the University College, Cardiff, for a degree course in medicine; Mavis Sheppard, of New Ollerton, Nottinghamshire, tenable at King's College, University of London, for an honours degree course in English; Gordon B. Skingle, of Chesterfield, Derbyshire, tenable at University College, Durham, for an honours degree course in modern languages; Graham Turner, of Shuttlewood, Derbyshire, tenable at Queens' College, University of Cambridge, for an honours degree course in natural science; Paul A. N. Wainwright, of Billinge, Lancashire, tenable at the University of St. Andrews, for a degree course in medicine.

Exhibitions:

Harry Allison, of New Herrington, Co. Durham, tenable at King's College, University of Durham, for an honours degree course in agriculture; Drummond H. Bowden, of Abercynon, Glamorganshire, tenable at the University of Bristol, for a degree course in medicine; Bridget Cairns, of Kelty, Fifeshire, tenable at the University of Edinburgh, for an honours degree course in physics; Henry P. Clement, of Willington, Co. Durham, tenable at King's College, University of Durham, for an honours degree course in chemistry; Kathleen M. Dawson, of Newbiggin-by-Sea, Northumberland, tenable at St. Hilda's College, University of Durham, for a course for the diploma in education; David Jenkins, of Llanharan, Glamorganshire, tenable at the University College of Wales, Aberystwyth, for an honours degree course in geography; Betty M. Linford, of Royston, Yorkshire, tenable at Newnham College, University of Cambridge, for an honours degree course in history; Jean M. McLachlan, of Girvan, Ayrshire, tenable at the University of Glasgow, for an honours degree course in chemistry; Henry A. Rigby, of Swinton, Yorkshire, tenable at Exeter College, University of Oxford, for an honours degree course in chemistry.

ERRATUM. In the article "Edmond Halley and Geomagnetism" in NATURE of August 28, on p. 232, col. 1, line 6, for "shell" read "skill".

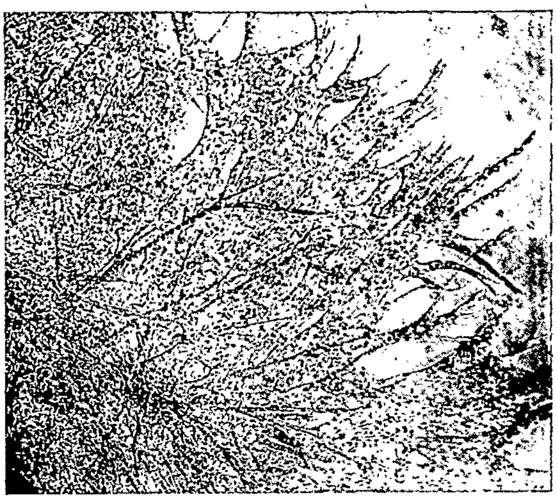
Long-term Cultivation *in vitro* of a Dibenzanthracene Mouse Sarcoma

ATTEMPTS to culture *in vitro* over long periods chemically induced sarcomas appear to have met almost universally with failure[1,2]. It seems therefore justified to report briefly on a pure *in vitro* strain of fibroblastic sarcomatous cells, derived from a dibenzanthracene mouse tumour, which was kept *in vitro* for slightly more than two years. The special architecture of these colonies described in a previous communication[3] was maintained with little variation throughout the culture period. The figure shows part of such a colony after 703 days of *in vitro* growth. The cultures were kept in Carrel flasks (coverslip passages, except in a few initial ones, were unsuccessful) in a dilute hen plasma coagulum containing 5 per cent chick embryo juice, and were fed twice weekly with a hen serum (0·2 c.c.)–chick embryo juice (0·05 c.c.)–Tyrode (0·55 c.c.) mixture. Transplantations were made according to the state of health, the cultures being examined daily. When the cultivation was discontinued, the strain had reached its thirty-eighth passage.

Great fluctuations in extent of growth and viability were experienced. As these cells practically fail to liquefy the coagulum, it was found essential to ensure a removal—as thorough as possible—of the aged adherent plasma clot because of its inhibitory action[4]. This was achieved either by mechanical manipulation under a dissecting microscope or by a short trypsin digestion as used by Vogelaar and Erlichman[5] for other types of cultures. The latter treatment was sometimes followed by a quicker and more vigorous outgrowth, and sometimes by complete disintegration; a number of cultures were lost in this way. The presence or the gradual formation in some sera of a substance toxic to these tumour cells, but not to homologous macrophages, was another source of danger to the life of these cultures. Therefore samples of different sera had to be kept in store. If the cytolytic action of a serum was discovered in time when only the peripheral cells had been affected, replacement of the deleterious serum by an innocuous one would result in recovery and save the cultures. The latent period (that is, time elapsed until the first cells wander out into the new coagulum), which is only a few hours from fresh tumour explants, became considerably lengthened with life *in vitro*, and was, during the last months, two days or more, during which time the cultures look almost like dead pieces of tissue.

The rate of *in vitro* growth is very slow compared with normal chick embryo fibroblasts. Area measurements made on sister cultures showed a fair agreement which would encourage closer quantitative work on these cultures were it not for the great difficulty of having cultures available in sufficient numbers. At its best the strain comprised about thirty cultures at a time, all derived from a single original culture.



SARCOMA CULTURE (*Fl* 10385*b*) LIVING, AFTER 703 DAYS *in vitro*; 31ST PASSAGE, 10 DAYS AFTER LAST TRANSFER. × 55.

Inoculations made from time to time of cultures into mice reproduced in some instances the original sarcoma, but the frequency of takes decreased with time of *in vitro* cultivation. After 393 days of *in vitro* growth, even a massive dose (5 cultures per mouse) injected into three animals failed to produce a tumour. The impossibility of increasing the strain substantially during the second year of cultivation prevented further inoculation tests apart from two cultures which were finally left and injected into a mouse; again no tumour resulted. It is difficult to account for these failures. Neither Ludford's[2] contention that the presence of macrophages is an essential feature in the invasive growth of tumours, nor Earle and Voegtlin's[6] tentative suggestion, put forward in a slightly different context, that the foreign medium employed might be responsible for the lack of takes, seems to afford a tenable explanation, as repeatedly some sarcomas were produced, in these studies, from pure fibroblastic sarcomatous colonies grown in an entirely heterologous medium during the first year. It seems possible to relate the failure of takes to the very long latent period observed *in vitro* after transplantation. If there is a similar delay after inoculation into an animal, the culture cells might die before they gain a foothold and/or the animal would be enabled to mobilize in sufficient strength its defence apparatus (leucocytes and antibodies) to cope effectively with the culture material introduced. Alternatively, it has to be assumed that the sarcoma cells have lost their malignancy or what power of autonomous growth they possessed. It must remain for future investigations to throw light on this problem.

I wish to thank the Birmingham Branch of the British Empire Cancer Campaign for a grant which supported this work.

A Serum that Discloses the Genotype of some *Rh*-Positive People

THE blood-group antigen *Rh*, present in the red blood cells of about 85 per cent of normal people, called *Rh*-positive, and absent in the rest, *Rh*-negative, plays, with its corresponding anti-*Rh* agglutinin, an important part in the causation of erythroblastosis fœtalis, a familial disease of the new-born. In about 90 per cent of cases of the disease the mother is *Rh*-negative and has made anti-*Rh* which passes through the placenta and damages the red blood cells of her *Rh*-positive fœtus. The *Rh* factor is inherited as a dominant character with three genotypes *RhRh*, *Rhrh* and *rhrh*.

Recently we have found in the serum of the *Rh*-positive mother of an erythroblastotic baby an agglutinin capable of disclosing the genotype of some *Rh*-positive people. This serum, sent to us by Dr. A. J. McCall as containing anti-*Rh* and yet being from an *Rh*-positive mother, we call *St* from the first two letters of the mother's surname. It reacts with the blood of all *Rh*-negative and of all heterozygous *Rh*-positive persons, *Rhrh* (recognized by being *Rh*-positive parents or children of *Rh*-negative subjects), but it fails to react with about 20 per cent of bloods all of which must, therefore, be homozygous, *RhRh*, and represent about half of the *Rh*-positive homozygotes (about 38 per cent of the population). The *St* serum is somewhat similar to the anti-*Hr* serum found by Levine, Javert and Katzin, and referred to by Wiener[1]. The latter serum, like *St*, reacted with all *Rh*-negative bloods, but whereas *St* failed to react with only 20 per cent, the anti-*Hr*, apparently, failed with about 50 per cent of people[2]. Our findings with *St* serum, and family details, are given below.

	St+	*St*—	Total
General population	173	45	218
Rh-negative bloods	100	0	100
Rh-positive heterozygous bloods	32	0	32

Mrs. St.	*O.MN. Rh+. St—.*
Mr. St.	A_1*.MN. Rh+. St+.*
Eldest son	*O.N. Rh+. St+.*
2rd son	Died of erythroblastosis fœtalis.
3rd son	*O.MN. Rh+. St+.*, recovered from erythroblastosis fœtalis.

It follows that certain rules can be formulated concerning parentage in general:

(*a*) An *St*-negative child must have both parents *Rh*-positive. (*b*) All children of an *St*-negative parent must be *Rh*-positive.

In families with erythroblastosis fœtalis due to anti-*Rh*:

(1) All mothers and children must be *St*-positive. (2) The only member who can be *St*-negative is the father. We have found no exception to these rules. (3) The father will be more frequently *St*-negative, since he is always *Rh*-positive, than will fathers of normal children. (4) If a father is *St*-negative he must be homozygous, *RhRh*, and so cannot produce an *Rh*-negative child. His chance of producing a child without the disease is, therefore, extremely remote. (5) If the great majority of fathers of erythroblastotic infants are homozygous, a conclusion to which we and our collaborators have been led by other observations[3], about half of them should be *St*-negative. We have so far found eight out of twenty-one to be *St*-negative. The examination of a larger number should show the extent of any preponderance of homozygous fathers.

There is ample evidence that there occur subgroups of *Rh* somewhat similar to those of the *ABO* system of groups, and to explain the findings that have been reported[1-4], it is certainly necessary to postulate three allelomorphic genes (Rh_1, Rh_2 and *rh*) and almost certainly four (Rh_1, Rh_2, Rh_3 and *rh*). It is tempting to equate the frequency of the genotype Rh_1Rh_1 to 0·20, the proportion of people whose cells fail to react with the *St* serum. If the frequency of the gene Rh_1 is so derived, it may be estimated that people of the genotypes Rh_2Rh_2 and Rh_2rh form about one sixth of all *Rh*-positive persons. It is noteworthy also that Wiener[1], from the behaviour of an anti-*Rh* serum that failed to react with about 16 per cent of *Rh*-positive bloods, thought that one sixth of all *Rh*-positives belonged to the 'subtype' Rh_2.

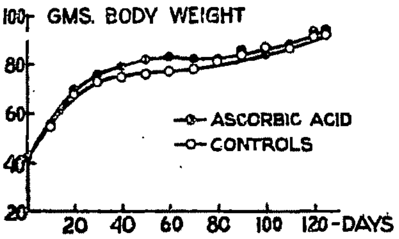
Vitamin C Requirements of the Syrian Hamster

WHILE engaged in some endocrinological and immunological work on the Syrian hamster, we became interested in the diet of this animal. It was thought of interest to examine the ascorbic acid requirements of the hamster, because if the animal required this vitamin, the hamster might be a useful animal for vitamin C studies since it reproduces and matures so rapidly, and is susceptible to many infections not easily produced in other animals. Since we started this study, Routh and Houchin[1] have concluded that thiamin, riboflavin, pyridoxin, pantothenic acid and nicotinic acid are essential in the diet of the hamster, while Cooper, Waisman and Elvehjem[2] have concluded that biotin and possibly inositol and *p*-aminobenzoic acid, in addition to thiamin, riboflavin, pantothenic acid, pyridoxin, and choline, are essential to the hamster, but that nicotinic acid and ascorbic acid are not. Since no growth curves have been published, we think the present study would be of interest.

The experiments were limited to the single substance ascorbic acid, using a diet containing adequate amounts of other growth essentials.

Procedure: Twenty male hamsters 3–5 weeks old were obtained from a commercial dealer (Henry Bergman, Springfield, Missouri). They were divided into two groups of ten each and of equal weight distribution, average body weight 42 gm., and fed *ad libitum* on a diet with and without added ascorbic acid. The diet was of the following composition:

Dextrose (corn sugar)	50
Casein (vitamin-free)	20
Dried brewer's yeast	10
U.S.P. 11 salt mixture	2
Cod liver oil	2
Corn oil (Mazola)	9
Lard	7
	100



GROWTH-RATES OF MALE HAMSTERS WITH AND WITHOUT DIETARY ASCORBIC ACID.

The diet was made in one kilogram lots at a time, and divided into halves. To one half (500 gm.) was added 3·5 gm. of ascorbic acid. The diet was stored under refrigeration and was analysed for ascorbic acid periodically. At no time did the ascorbic acid content of the diet drop below 4 mgm. per gm. The diet was offered in small porcelain feeders (the "Fisher feeder"). One group was fed the diet plus ascorbic acid, and the other group was fed the plain diet. The food intake and animals were weighed daily for the first week and then every other day until the termination of the experiment. The ten animals of each group were caged together.

Results and conclusions: The accompanying graph shows the average growth-curves of the twenty male hamsters on the diet with and without ascorbic acid. The food intake averaged 3·5 gm. per animal per day after the first thirty days of the experiment, making the ascorbic acid intake of the ascorbic group at least 14·0 mgm. per animal per day. There was no appreciable difference in the growth-curves, health and appearance of the two groups. The average weight increase for the first thirty days was 1·07 gm. per day, as compared with 1·05 gm. per day quoted by Cooper *et al.*[2] for hamsters on a synthetic diet. From this it was concluded that the hamster does not require the addition of ascorbic acid to its diet. Others[2,3] have made the same observation, but no growth-curves were presented.

The investigation was supported in part by a grant from the Graduate School of the University of Minnesota. We wish to express our thanks to Marion B. Clausen for her assistance in caring for the animals, and Mr. John Kaster, who determined the ascorbic acid content of the diets.

A Dimastigamœba in the Bed of the Dead Sea

PROFILES of mud samples taken from different places and depth in the Dead Sea were inoculated nto enrichment cultures prepared in Detmer media, 1 : 2, containing different salt concentrations: 0, ½, 1, 3, 6, 9, 12, 15, 18, 25, 75 per cent Dead Sea water and also in Dead Sea water. All the cultures were exposed to electric light; temperature, 25–30° C.

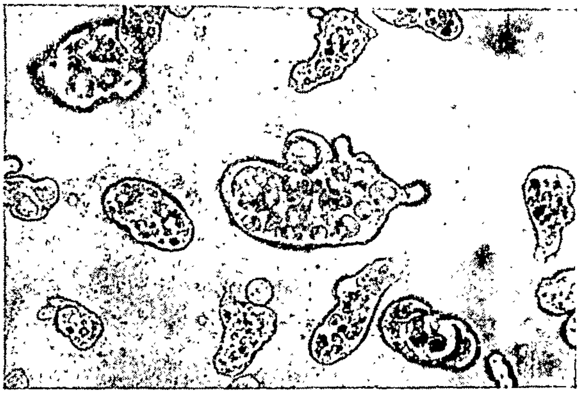

Fig. 1. DIMASTIGAMŒBA OF DIFFERENT SHAPE AND SIZE FROM AN ENRICHMENT CULTURE INOCULATED WITH MUD SAMPLES TAKEN AT A DEPTH OF 330 M. UNSTAINED PREPARATION. × 360.

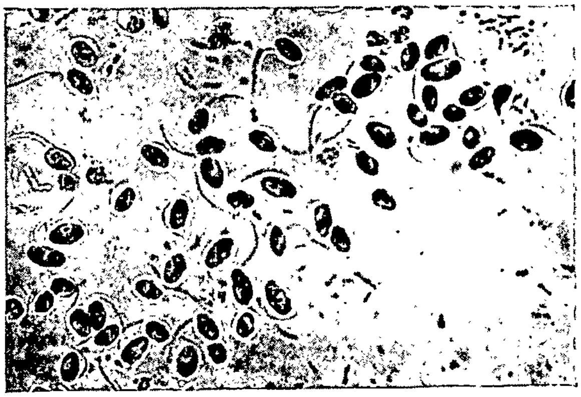

Fig. 2. GREEN FLAGELLATES WITH A SINGLE FLAGELLUM ARISING FROM THE SIDE OF THE CELL. UNSTAINED PREPARATION. × 800.

Rich growth of blue-green algæ was seen in the different salt concentrations. In most of the mud samples the phytoflagellate *Dunaliella viridis* Teod., previously described[1,2], was found. In addition, a very similar green flagellate with a pink eye spot at the posterior end was isolated from a mud sample taken from a depth of 315 m.

In four of the enrichment cultures containing 9, 12, 15, 18 per cent salt, and inoculated with a mud sample from a depth of 330 m. (s.g. 1·222; temperature, 17·5° C., total salt, 31·6 gm. per 100 c.c.), rich growth of amœbæ and cysts were observed after 2½–3 months.

The amœba (Fig. 1) lives in association with a green flagellate and a blue-green algæ. The small green flagellate (Fig. 2)—2–3μ × 4–6·5μ—has a single flagella arising from the side of the cell and a small pink eye spot. The organism is very actively motile with the flagella in its back. The blue-green alga appears in single cells, pairs or short chains, and probably belongs to the genus Aphanocapsa.

The amœbæ vary much in size from 7–54μ by 17–80μ. They are fairly actively motile.

The amœba readily grows in the light in Detmer media, 1 : 2, containing 15 per cent salt plus 15 per cent Dead Sea mud plus 0·02 per cent peptone. Its main food is the green flagellates and the blue-green algæ; cannibalism is rather common.

It was possible to grow the amœbæ in the dark in a semi-solid medium (2 parts agar 3 per cent plus 8 parts liquid media) containing Detmer 1 : 2—15 per cent salt, 0·02 per cent peptone, and a very small

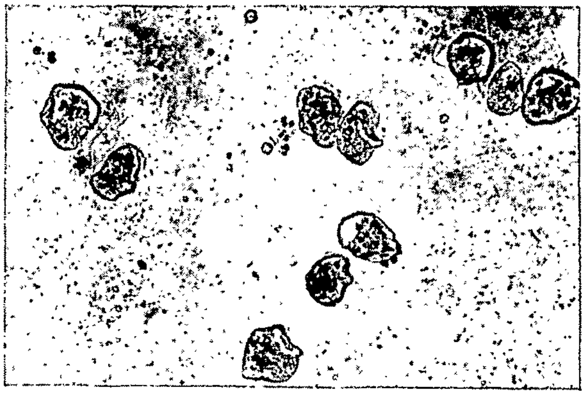

Fig. 3. A FLAGELLATE STAGE OF THE DIMASTIGAMŒBA. UNSTAINED PREPARATION. × 360.

amount of rice starch which was added before inoculation ; temperature, 30° C.

The optimum salt concentration is 15–18 per cent. However, the amœbæ survive in saturated solution ; they multiply slowly in 6 per cent salt.

The characteristic feature of the amœba is its ability to develop flagella under still undetermined conditions and to behave as a flagellate. The flagellates are round or slightly oval (11–25μ × 16–27μ), having a cytostome and two, four, six or rarely eight flagella (Fig. 3). They are very actively motile.

Full details will be published elsewhere.

Numerical Fourier Analysis to Twenty-Nine Harmonics

THIS method uses material developed and made available by C. A. Beevers and H. Lipson[1] for computing Fourier syntheses, which has been found to be readily adaptable to the inverse process of analysis. It is applicable to the analysis of periodic functions in which the amplitudes of harmonic components of thirtieth and higher order are negligible. It gives resolution up to the twenty-ninth harmonic and amplitudes accurate to 1 per cent of the largest component.

The harmonic function $y(x)$ having period l may be written

$$y(x) = A_0 + \sum_n A_n \cos 2\pi n \frac{x}{l} + \sum_n B_n \sin 2\pi n \frac{x}{l},$$

in which the cosine series includes terms up to the thirtieth, the last being of negligible amplitude, and the sine series includes terms up to the twenty-ninth. This form of expression, and the number of constants included, is dictated by the method of analysis ; all quantities determinable by the method have been introduced into the equation. The problem of analysing the given function $y(x)$ resolves itself into the determination of the sixty quantities A_0 and all A_n and B_n.

By the method of Bessel[2], these sixty quantities may be determined when the values assumed by $y(x)$ are known (say to 1 per cent of the largest ordinate) for sixty values of x taken at successive intervals of a sixtieth of a period. Let the values of x be denoted by $\frac{ml}{60}$, where m assumes in succession al integral values in the range $0 \leqslant m \leqslant 59$, and let the known corresponding values of $y(x)$ be denoted by y_m. Bessel's solution is

$$A_0 = \tfrac{1}{60} \sum_{m=0}^{59} y_m;$$

$$A_n = \tfrac{1}{30} \sum_{m=0}^{59} y_m \cos 2\pi \frac{nm}{60},\ 1 \leqslant n \leqslant 29,$$

$$A_{30} = \tfrac{1}{60} \sum_{m=0}^{59} y_m \cos 2\pi \frac{30m}{60},$$

$$B_n = \tfrac{1}{30} \sum_{m=0}^{59} y_m \sin 2\pi \frac{nm}{60}.$$

Here A_0 may be written for purposes of computatio as

$$A_0 = \tfrac{1}{60} \sum_{m=0}^{59} y_m \cos 2\pi \frac{nm}{60},\ n = 0.$$

The quantities to be determined are summations o sixty terms, each of the form $C_m \begin{smallmatrix}\sin\\ \cos\end{smallmatrix} 2\pi \frac{nm}{60}$, wher n and m are integers such that $0 \leqslant n \leqslant 30$ an $0 \leqslant m \leqslant 59$.

The functions $C_m \begin{smallmatrix}\sin\\ \cos\end{smallmatrix} 2\pi \frac{nm}{60}$ are the function tabulated by Beevers and Lipson on their sine an cosine strips. Their values are given to the neares integer for all values of C_m from 1 to 99. The argu ment $2\pi \frac{nm}{60}$ is symmetrical with respect to n and m tabulated values of the functions are given for range of 0 to 15 for one integer and of 0 to 20 for the othe To use the strips for the purpose of analysis, eac strip may be taken as a row of entries for given C and m for all values of n from 0 to 15. Since th functions $\begin{smallmatrix}\sin\\ \cos\end{smallmatrix} 2\pi \frac{nm}{60}$ are either symmetrical or ant symmetrical about the value $n = 15$ according as tl functions are non-zero or zero for this value, tl extension of the functions to $n = 30$ can be mechani ally carried out at a convenient stage in the calcul tions.

The symmetries of $\begin{smallmatrix}\sin\\ \cos\end{smallmatrix} 2\pi \frac{nm}{60}$ about the valu $m = 30$ and $m = 15$ may be applied to reduce tl m-summations from 60-term summations to sun mations of 14, 15 or 16 terms taken over the fir quarter period of $\begin{smallmatrix}\sin\\ \cos\end{smallmatrix} 2\pi \frac{nm}{60}$. The symmetries are shown in the accompanying table.

Group \ m =	30	15	Amplitude notation fo quarter perio summations
Cos $2\pi \frac{nm}{60}$, n even	symmetrical	symmetrical	d_0 to d_{15}
,, n odd	symmetrical	anti-symmetrical	e_0 to e_{14}
Sin $2\pi \frac{nm}{60}$, n even	anti-symmetrical	anti-symmetrical	f_1 to f_{14}
,, n odd	anti-symmetrical	symmetrical	g_1 to g_{15}

Thus

$$(n \text{ even}) \sum_{m=0}^{59} y_m \cos 2\pi \frac{nm}{60} = \sum_{m=0}^{15} d_m \cos 2\pi \frac{nm}{60}$$

$$(n \text{ odd}) \sum_{m=0}^{59} y_m \cos 2\pi \frac{nm}{60} = \sum_{m=0}^{14} e_m \cos 2\pi \frac{nm}{60}$$

$$(n \text{ even}) \sum_{m=0}^{59} y_m \sin 2\pi \frac{nm}{60} = \sum_{m=1}^{14} f_m \sin 2\pi \frac{nm}{60}$$

$$(n \text{ odd}) \sum_{m=0}^{59} y_m \sin 2\pi \frac{nm}{60} = \sum_{m=1}^{15} g_m \sin 2\pi \frac{nm}{60}$$

The procedure is now as follows. Select from the box of strips the fourteen, fifteen or sixteen strips required for one group of summations. Separate these into two sets according as the value given on the strip for $n = 15$ is zero or non-zero and arrange the two sets separately for addition of the columns of constant n. If an n-even group is being worked, total the columns for $n = 0, 2, 4 \ldots$ in both sets; if an n-odd group is being worked, total the columns for $n = 1, 3, 5 \ldots$ in both sets. The totals for the two sets must be added according to columns to give the summations up to the fifteenth order of n. The totals for the two sets must be subtracted to give the higher orders of n in descending order, the anti-symmetric set being subtracted from the symmetric set.

The following simple checks are applicable (subsidiary checking is desirable for amplitude calculations and strip selection):

$$\sum_{n=0}^{30} A_n = y_0;$$

$$\sum_{n=1}^{29} B_n \sin 6n^0 = \tfrac{1}{2}(y_1 - y_{59});$$

$$\sum_{\substack{n=0 \\ n \text{ even}}}^{30} (-1)^{n/2} A_n + \sum_{\substack{n=1 \\ n \text{ odd}}}^{29} (-1)^{(n-1)/2} B_n = y_{15}.$$

The whole process of computing and checking can be carried through for twenty-nine harmonics in less than two hours. The method has proved satisfactory in regular use and has been found less tiring than the process of curve tracing necessary in machine analysis. Except for convenience in checking, no more harmonics need be determined than are actually required. The procedure can be quickly learnt, errors are not liable to occur, and the calculations, including checking, can be performed almost entirely on an adding machine.

[2] Whittaker and Robinson, "Calculus of Observations", pp. 264 *et seq.*

MISS ROSS has done a useful service in directing attention to the value of the Beevers-Lipson strips for the process of Fourier analysis. These strips were originally designed for Fourier synthesis in crystal-structure determination, and for this purpose printed copies have been supplied to some forty crystal-structure laboratories (a few copies of the uncut tables are still available from this address). It seems likely, however, that the application to Fourier analysis is of rather wider interest. Prof. Max Born suggested this use of the strips to us some years ago, but it was only after inquiries by other workers, and finally by hearing of the successful work of Miss Ross, that we have come to realize that the strips provide by far the most convenient practical method of Fourier analysis available in an ordinary laboratory.

The Fourier machine which we have recently described[1] will perform the same work as the strips, and would therefore carry out the process described by Miss Ross. It would enable the user to go from the numerical values of the y_m to the twenty-nine Fourier coefficients in a time of less than eight minutes. Even faster working would be permitted by a minor extension of the machine so as to attain a wave-number of 30 instead of 24 as at present, and a machine working with similar components but with thirty-one counters and going up to a wave-number of 60 would enable the operator to complete the whole process in about three minutes. There may be applications of Fourier analysis where this extreme speed is desirable. Checking could be readily carried out by re-synthesis of the function.

The process can be done, of course, on a commercial scale by the use of the Hollerith series of tabulating machines, but these are considerably slower than the Beevers machine, although they provide a flexible and reliable method.

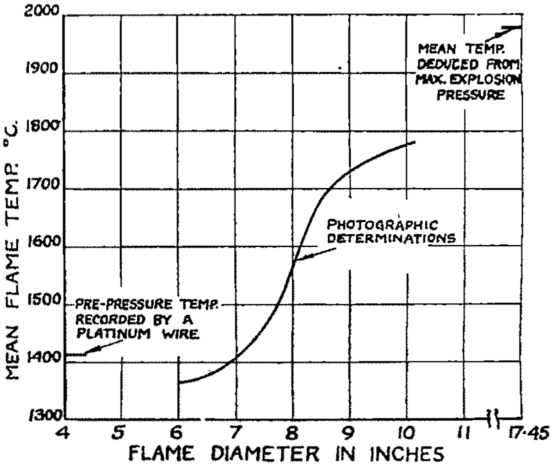
Temperature Gradients in Gaseous Explosions

A NEW method of determining flame temperatures during explosions in a closed vessel has been evolved. Briefly, the method consists of recording photographically flame travel and simultaneously, by means of a very sensitive diaphragm type of pressure indicator, the pressure rise in a large spherical explosion vessel 17·45 in. in diameter with central



ignition. By correlating flame diameter with pressure rise the mean gas temperature in the burnt portion could be deduced at different instants during the explosion (up to a limiting diameter of 10 in.).

The results obtained with a 10 per cent oxygen plus 90 per cent carbon monoxide mixture are shown in the accompanying graph. Also indicated is the pre-pressure flame temperature measured by means of a platinum resistance thermometer (which in the case of very over-rich mixtures registers the same temperature as a quartz-coated platinum resistance thermometer[1]) and the maximum mean gas temperature obtained from the maximum explosion pressure[2].

It will be noted that the mean temperature rises from a value very much in line with the platinum wire temperature at a diameter of 6 in. up to a value, at 10 in. diameter, approaching the mean temperature inferred from the maximum pressure. This shows that the latent energy[3] in the flame gases diminishes as the flame travels outwards from the spark.

Direct experimental confirmation of David's postulate[4] that the latent energy diminishes with distance of flame travel from the igniting source is thus furnished by the experiment.

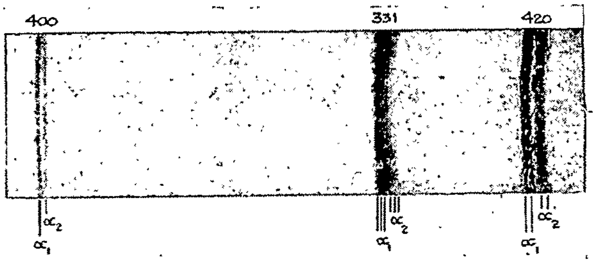
Structure of Nickel Oxide

The development of modern X-ray powder photographic methods has opened up new possibilities for the examination of the fine structure of crystalline substances. The high resolution and definition of the reflexions, particularly in the high-order lines, which is obtainable with such circular cameras as that described by Bradley, Lipson and Petch[1], has not only meant an increase in accuracy of lattice parameter measurements, but has also enabled interesting phenomena in alloys to be observed[2]. The detection of extra reflexions in powder photographs of graphite[3] has led to the description of a second crystalline form[4], which apparently co-exists with the structure established by Bernal.

Another instance, which depends upon the observation of the fine structure of powder lines, has been noticed during an examination of nickel oxides from various sources. The structure for nickel oxide determined by Cairns and Ott[5] is face-centred cubic with $a_0 = 4{\cdot}1684$ kX., the atomic arrangement being of the sodium chloride type; the lines on a powder photograph taken on a small-diameter camera are distributed in the usual way for a face-centred cubic substance. Photographs of well-crystallized specimens taken on a 19-cm. diameter camera giving highly resolved reflexions show, however, that many of the lines are not simple α-doublets, but are doubled or in some instances tripled. The type of reflexion obtained is shown in the accompanying illustration, which is a reproduction of the high-order end of the pattern with cobalt $K\alpha$-radiation.



Part of X-ray powder photograph (calcium $K\alpha$-radiation, 19 cm. camera) of nickel oxide. × 2.

Photographs taken with various radiations, to enable a sufficient number of (hkl) reflexions to be analysed, indicate that all lines are doubled or have more than one α-doublet component except those with indices $(h00)$.

If the structure of nickel oxide departs very slightly from cubic symmetry in a manner that makes it rhombohedral, the observed modifications of the reflexions can be explained. The distortion is so small that it is difficult to ascertain with complete certainty whether the angle of the unit rhomb is greater or less than the theoretical for cubic symmetry, but a larger value seems most probable when the intensities and separations of the components of all the observable reflexions are taken into account. On this assumption the most probable values for the lattice parameters of the rhombohedral unit cell are, at 20° C., $a_0 = 2{\cdot}9459$ kX., $\alpha = 60° \, 4{\cdot}2'$.

The effect has been observed for nickel oxides of widely different origins, including a variety commonly known as 'black nickel oxide', and is noticeable with feebly crystallized specimens in spite of some broadening of the reflexions owing to small crystal size. It is not obtained with monoxides of the other transition elements iron and cobalt, and indeed the solution of relatively small percentages of these oxides in nickel oxide causes a reduction in separation of the components of the complex reflexions. The asymmetry of the structural unit of nickel oxide may therefore be associated with the slightly smaller effective size of the nickel atom as compared with iron and cobalt; the atomic packing is affected in such a way that there is the equivalent of a small compression of the cubic lattice along a triad axis.

There may well be other crystals, that to a first approximation appear to conform to the isometric system, but would in fact on precision examination be found to possess a less simple structure. Latest refinements in powder photographic technique which permit the fine structure of the reflexion lines to be studied may yield interesting results in this connexion.

SOME EFFECTS ON LIESEGANG RINGS

By DR. H. FRIEDEBERG,
Sunfield Lab., Clent, nr. Stourbridge

THE observations described below were made in the course of investigations carried out under the auspices of the Sunfield Agricultural Centre, Clent (now the Agricultural Centre, Blairs, Aberdeen), on the sensitivity of Liesegang rings to various influences, undertaken with the view of applying them to certain biological problems.

Formative Catalysis

Liesegang[1] uses the term *Formcatalysator* for potassium dichromate when, through a double reaction, it brings about rings of silver chloride not formed without its presence.

We observed two cases of formative catalysis causing stratification of manganese sulphide. When ammonium sulphide solution is allowed to diffuse into gelatine containing manganese chloride in a test-tube, the latter is deposited almost homogeneously. If small amounts of stannous chloride or copper sulphate are added to the manganese chloride – gelatine, distinct layers separated by completely clear spaces are formed. In the case of stannous chloride the layers begin 8–25 mm. below the surface of the gelatine and continue to be formed throughout the length of the test-tube. Their thickness and the distance between them increase in a regular way similar to the silver chromate layers. The minimal concentration of stannous chloride producing the effect is 10^{-5}, the concentration of the manganese chloride being 10^{-3} and that of the ammonium sulphide 1–2 per cent. Higher concentrations of stannous chloride produce more and thinner layers. The manganese sulphide layers due to the action of copper sulphate begin farther down the tube where diffusion is rather slow. The minimal concentration of copper sulphate still active is 10^{-6} (manganese chloride 10^{-3}, ammonium sulphide 1–2 per cent). In both cases the concentration of the formative catalyst must be increased if higher concentrations of manganese chloride and ammonium sulphide are used.

This effect cannot be explained by a double reaction as in Liesegang's experiment. Stannous chloride and copper sulphate alone form no layers with ammonium sulphide, and the necessary quantities are very small—2·5 γ $Cu^{\cdot\cdot}$ in 10 ml. gelatine, which is of the order of the Feigl spot-test limits.

Of other metal salts, sodium arsenite and chromium sulphate show a similar effect with manganese sulphide, but much weaker than $Cu^{\cdot\cdot}$ and $Sn^{\cdot\cdot}$; $Fe^{\cdot\cdot\cdot}$, $Pb^{\cdot\cdot}$, $Ni^{\cdot\cdot}$, $Co^{\cdot\cdot}$, $Ba^{\cdot\cdot}$, $Mg^{\cdot\cdot}$, $Hg^{\cdot\cdot}$, $Hg^{\cdot}$, $Ag^{\cdot}$, $Zn^{\cdot\cdot}$, $Cd^{\cdot\cdot}$ are inactive.

We observed also a case of negative formative catalysis: lead salts interfere with or prevent the formation of silver chromate layers when added to silver nitrate–gelatine into which potassium dichromate is diffusing. The effect is noticeable with a lead salt concentration of 10^{-5} and stratification is completely prevented at 10^{-4} (silver nitrate 0·5 per cent, potassium chromate 5 per cent). Sodium arsenite at concentration 10^{-4} also prevents formation of silver chromate layers, whereas $Cu^{\cdot\cdot}$, $Sn^{\cdot\cdot\cdot\cdot}$, $Cr^{\cdot\cdot\cdot}$, $Mn^{\cdot\cdot}$, $Zn^{\cdot\cdot}$, $Cd^{\cdot\cdot}$, $Ca^{\cdot\cdot}$, all at concentration 10^{-4}, have no effect. $Fe^{\cdot\cdot\cdot}$ and $Hg^{\cdot\cdot}$ cause a slight disturbance. A similar effect of lead salts at concentration 10^{-4} could be observed in the case of manganese hydroxide layers (8 per cent ammonia diffusing into gelatine containing 0·5 per cent manganese chloride). Here, too, other metals are far less active ($Cu^{\cdot\cdot}$, AsO_3''', $Sn^{\cdot\cdot}$) or inactive ($Ag^{\cdot}$, $Hg^{\cdot}$, $Hg^{\cdot\cdot}$. $Zn^{\cdot\cdot}$, $Cd^{\cdot\cdot}$, $Sn^{\cdot\cdot\cdot\cdot}$, $Cr^{\cdot\cdot\cdot}$, $Ba^{\cdot\cdot}$, $Mg^{\cdot\cdot}$). Other influences, acidity, alkalinity, oxidizing and reducing agents require a higher concentration in order to interfere with the manganese hydroxide layers.

Effects of Mercury Vapour

When a piece of metal sheet (zinc, iron, tin, lead or copper), either superficially amalgamated by spreading mercury on its surface or treated with mercuric chloride solution, is placed 3–5 mm. above a glass plate bearing a layer of 5 per cent gelatine containing 0·1 per cent potassium dichromate in the centre of which a drop of 50 per cent silver nitrate solution has been placed, the silver chromate rings are affected. The plate should be covered and left for 20–30 hours. Three different effects can be observed:

(1) Serious disturbance of the rings, the silver chromate being partly deposited homogeneously or in irregular patches. This effect has been described by Shemyakin[2]. (2) Intensification of the micro-rings. (3) Formation of a new structure on the surface of the gelatine. It consists of straight lines proceeding in a radial direction strictly perpendicular to the micro-rings. There are about 100–150 of them to the millimetre and they can be clearly seen under the microscope. The optical effect is visible to the naked eye as soon as the plate is uncovered after the experiment. Acting as a diffraction grating, a bright spectrum is produced in reflected as well as in transmitted light. Exposure of the plate to mercury vapour for a short period shows that the formation of these radial lines takes place only at the periphery of the expanding diffusion circle. Besides the radial lines, wrinkles are also produced on the gelatine surface. The phenomenon is not of a stable nature and the radial lines get very faint some days after the experiment.

So far the effect has been observed only under the influence of mercury. Lead, iron, tin, zinc, copper, nickel do not produce it. This seems to indicate that it is due to action of the vapour and not to a radiation as suggested by Shemyakin[2].

Effects of Temperature, *p*H, and Light

The structures formed by diffusion of silver nitrate into potassium dichromate–gelatine are influenced by temperature, *p*H and light. In all three cases the effects on the layers are opposite to those on the micro-rings. The concentrations used for these experiments were: 5 per cent gelatine containing 0·1 per cent potassium dichromate; 8·5 per cent silver nitrate as diffusing solution.

Effects on the layers. Increasing temperature promotes layer formation. Whereas only a few layers appear at temperatures between 0° and 10°, a complete series from the gelatine surface down the tube is obtained above 15°.

Alkalinity promotes layer formation at low temperature (0°–10°), where a complete series can be obtained by adding 0·02 per cent sodium hydroxide to the gelatine. Higher alkalinity (0·04 per cent sodium hydroxide) brings about continuous precipitation, but above 0·05–0·06 per cent sodium hydroxide layers are again formed up to 0·3 per cent. Above that concentration continuous precipitation again takes place. Acidity shortens the range of the layers with increasing concentration, leaving only the top ones, and layer formation is prevented altogether above 0·15–0·2 per cent sulphuric acid.

Light at temperatures below 10° slightly reduces the number of layers. At higher temperature no such effect takes place.

Effects on the micro-rings. The formation of micro-rings is disturbed and eventually prevented with increasing temperature. Alkalinity also has a disturbing influence and above 0·04 per cent sodium hydroxide no micro-rings are formed. Acidity promotes the formation of micro-rings, the optimal concentration being 0·02–0·12 per cent sulphuric acid. At higher concentrations their range is reduced and above 0·3 per cent sulphuric acid none is formed.

The most striking influence on the micro-rings is that of light. It is strongly positive and seems to be almost indispensable for their formation. This, however, could not be definitely established; as a few micro-rings near the gelatine surface have been observed in some experiments conducted in the dark even if the chromate gelatine had been prepared in the red light of a photographic developing lamp. But it is certain that at room temperature, with the concentrations mentioned, no micro-rings are formed more than 20 mm. from the gelatine surface without the action of light. If such an experiment, after having proceeded in the dark for at least twenty-four hours, is exposed to strong light for a limited time, micro-rings are formed beginning from the level to which diffusion has gone. Their formation does not cease when the light is removed but continues in the dark for a period the length of which depends on the intensity of the light and the duration of the exposure.

A chromate gelatine containing 5 per cent gelatine, 0·1 per cent potassium dichromate and 0·03 per cent sulphuric acid was prepared in red light and poured into test-tubes which were kept in the dark. On the following day, 8·5 per cent silver nitrate solution was poured on top of the set gelatine. After thirty hours the tubes were exposed to various kinds of light with the following results:

Light source	Time of exposure	Width of belt of micro-rings	Approx. time of micro-ring formation
150-watt bulb at 50 cm. dist.	2 hr.	No micro-rings	—
Daylight	20 min.	No micro-rings	—
Daylight	40 min.	2 mm.	3–4 hr.
Daylight	60 min.	3 mm.	5–6 hr.
Quartz lamp at 25 cm. dist.	7 min.	2 mm.	3–4 hr.
Quartz lamp at 25 cm. dist.	17 min.	20 mm.	2 days

This after-effect of light can be explained by a photochemical change of the chromate gelatine by which conditions for the formation of micro-rings are produced, and which is slowly reversed in the dark. The change itself also seems to take some time if the light is not very strong. In the case of daylight, not with the quartz-lamp, the micro-rings did not appear immediately upon exposure but 1–2 mm. farther down.

We wish to express thanks to the members of the service scheme of the Agricultural Centre, Heathcot House, Blairs, Aberdeen, for their financial help, which has enabled us to carry out the present work.

SCIENCE UNDER FASCISM AND DEMOCRACY

AT a Conference organized by the Association of Scientific Workers (West Midland Area) in Birmingham, on August 22, scientific workers from nine nations contrasted the position of science, and scientific workers, in countries under fascist and democratic regimes.

The chairman, Dr. W. Wilson, emphasized that the war effort of the United Nations had depended to a very high degree upon the work of men of science, and if the prosperity and health of the world was to be ensured after the War then the role of the man of science would be no less important. Science, however, can only be expected to flourish in a social and political atmosphere which allows freedom of thought. The Lord Mayor of Birmingham (Councillor W. S. Lewis) tendered a civic welcome to the assembled delegates, and expressed the hope that it would be speedily possible to re-establish the scientific life and culture of the occupied countries in Europe which the Nazis are now trying to destroy.

In a message to the conference, Prof. Semon Sarkisov said that the German invaders had already felt the strength of Soviet science in the blows struck by the Red Army. Thanks to their peace-time achievements, and intensive war-time activity, the men of science had enabled the resources of the Urals, Siberia, and Kazakhstan to be put into effective use for the country's war effort. In the sphere of agriculture they had been able to move successfully a number of essential crops from the Ukraine to the eastern regions of the U.S.S.R. Dr. Goebbels had said: "Humanism, culture, and international law are empty words for us". Was it, then, a wonder that German medical science, for example, had not produced anything new for the benefit of mankind during the period of Nazi rule, but on the contrary it had rapidly declined? Hatred of mankind was the basic feature of fascism, which aimed at enslaving the peoples of the world by using a pseudo-scientific ideology based on the would-be superiority of the German race.

A. van Anrooy (Holland) gave an account of the historical growth of science in Holland under the liberal regimes of the seventeenth and eighteenth centuries, this leading to many famous medieval inventions. The Universities of Leyden and Delft had become famous throughout the world, but under the rule of Seiss Inquart they have been closed and the student organizations disbanded. Dr. C. Koeck, speaking for Austria, outlined the disastrous results upon the scientific life of Vienna of the occupation by the Nazis, since science is merely of secondary importance under fascism.

Prof. J. H. Hildebrand (United States) gave personal impressions of German science gained during visits paid to Germany under the regimes of the Kaiser, Republic, and the Nazis, and instanced many scientific absurdities perpetrated by "Aryan scientists". A totalitarian regime cannot permit any challenge to its power, and the freedom to seek and speak the truth is a danger against which it must always be suspicious. Benevolent, enlightened despots have been very few. Men of science must add a fifth freedom to their charter: "the freedom to exercise unquenchable curiosity". They must not be bribed by any false promises of political Messiahs who might interfere with their freedom to seek the truth; they must insist upon asking questions and getting their answers from Nature rather than from a Dr. Goebbels.

Dr. B. Schober (Czechoslovakia) gave details of the destruction of Czechoslovak scientific culture since Nazi occupation, and the persecution of the students and professors following their resistance to fascist domination. The health of the nation is deteriorating rapidly since the food supplies available provide only one- to two-thirds of the essential calories. Mr. P. M. Yap contrasted the scientific spirit in China and Japan, showing that the Japanese treatment of science follows very closely that of Germany. Full scientific progress in China has been retarded in the past by its dependence upon political and social conditions, but at present these are highly favourable and science is receiving the support of both Government and people. Mr. J. J. Ducenne dealt with the general position of science in Belgium before the War, and then gave impressions of the struggle between men of science and the occupying Nazis.

Prof. J. B. S. Haldane paid a tribute to the scientific workers who had been able to escape from occupied countries and were giving us inestimable help in our destruction of fascism. He then dealt with science in the U.S.S.R., stating that the system of planning had enabled the country to mobilize all men of science for the war effort much more quickly than we could. Planning was done largely by men of science in the U.S.S.R., and it was important to realize that the present power of the Red Army was due to scientific planning in the past, particularly in geological research, which employs some two thousand trained geologists. He thought that undoubtedly the Soviet Union had something to learn from Great Britain regarding liberty; similarly we might learn a lot from the Soviets about planning. It was all-important that we should learn how to combine planning and freedom, for that was the key problem of the future. It must be realized that scientific workers are skilled manual workers, and we must resist any attempt by educationists to make a gap between the two. The utmost scientific knowledge must be given to ordinary people.

Dr. G. Fournier (France) showed that it was impossible for the man of science to live remote from politics and the affairs of the world. Too many men of science had said: "I am not interested in politics". Now the politicians have become too interested in the men of science, and as a result many had found themselves in custody, and their books burnt. Science has a social value and the man of science cannot wash his hands of his discoveries. It is his duty to see that they are used for the betterment of mankind, and not for ts destruction. In future he must be continuously alert to ensure that fascism does not reappear under some other name elsewhere in the world.

Dr. J. G. Siebert (Germany) summed up the discussion, and by resolution the meeting sent its greetngs to peoples in subjected countries, and expressed the view that, as rational organization of science for the purpose of waging war would bring victory over the Axis powers, a thorough co-ordination of scientific and technical enterprise could forge weapons to destroy the evils of want, disease, and ignorance which would still have to be confronted when the War was won. The meeting pledged fullest support for 'the impending large-scale decisive invasion of the European continent. We call on all scientists and echnicians to give of their utmost, whether in workshop or in hospital, in laboratory or at the battlefront".

J. S. CLIFF.

CIVILIAN CONTRIBUTION TO EDUCATION IN THE FORCES

THE Report of the Central Advisory Council for Education in H.M. Forces for the period October 1942–March 1943 again directs attention to the remarkable way in which the project is growing. Much of the increase in demand can be explained by the introduction of compulsory educational periods in the Army during training hours for the months November–February. This not only increased the desire for supplementary lectures by experienced civilians but has, principally in Anti-Aircraft Command, called for aid from the university and university college regional committees in giving the suggested talks on citizenship in a number of small units which do not possess suitable teachers within their ranks. Steps taken by the Royal Air Force, and more recently by the Royal Navy, to encourage the study of current affairs, account for an increase in educational activities by these Services proportionately greater than that for the Army.

There has been an increased demand for lectures and classes by many women's units. Efforts have been made to meet this demand by adding lecturers to regional panels who are particularly well equipped to give the personal approach and treatment of subject which is required by audiences of women. At one A.T.S. conference it was revealed that arranging education in women's units is often more difficult than in men's units, but that the A.T.S. could do much more in the way of education if the right subjects and approach could be found. A profitable introduction to citizenship was being made in women's units through their interest in social services.

An interesting development has been the increase in the number of "site visitors". These are men and women who visit small units at regular intervals to guide and advise units on many social and educational matters. Usually the visit takes the form of an informal talk or discussion and is often followed by requests for help or information in regard to all kinds of group or individual activities. The voluntary organizations connected with education have contributed greatly to the success of these site visits.

People who are interested in the development of residential colleges for adult education for the civilian population will find much to interest them in the short schools and conferences which were arranged by the regional committees for H.M. Forces. In the period under review, 126 of these courses, etc., were held, 44 of them being residential. They were attended by 4,398 Service men and women, including members of the U.S. Forces. One of these courses was of three weeks duration and dealt with the basic elements of responsible citizenship, while other courses of the same nature lasted for shorter periods. The experiences gained during these periods of residential study should be of great value to educationists connected with adult work in the post-war period. It should be pointed out that similar courses were arranged for men and women from the Dominions, the fighting services of other members of the United Nations and the merchant navies of Britain and other countries.

The statistics issued in this report show that the number of single lectures given by civilian lecturers was 61,546, an increase of 44 per cent over the previous six months. The number of short courses increased by 15 per cent to 3,223, while the number of continuous classes rose to 1,369, an increase of 35 per cent.

Topics of current interest were responsible for much of the increase, while the increase in non-vocational science and psychology (classified separately) was very considerable. Handicrafts again proved popular and increased in number, but the shortage of materials has hindered the formation of classes in a number of crafts.

The growing volume of work undertaken by the regional committees is a tribute not only to all the individuals who take part in the work but also to the Service authorities for their wisdom in encouraging educational activities among serving men and women.

PROPOSALS FOR NEW BASIC PHYSICAL POSTULATES

IN a series of papers published in 1942, some in the *Manual of Myiology*, Dr. H. T. Townsend, of S. Paulo, Brazil, puts forward a revolutionary set of new physical theories. While there does not appear to be adequate evidence for the views put forward in the papers under notice, the following are principal postulates, mainly in the author's own words:

Centrifugal force is inherent in all cosmogen (mass + motion) and is the most basic cosmic force. Gravity is an equally basic cosmic force. Hence the two are one and the same force. Gravity is the complement of bound centrifugal force. It is unbound centrifugal force. Centrifugal force makes up all cosmogen by its interaction with the actinionic medium. Spinning actinions spinning round a vortex centre are the basis and the electron formed from them spins inherently. Spinning atoms are formed from spinning electrons and spinning molecules from spinning atoms. Centrifugal force centres vary from innumerable microfield centres (vortices in the medium) to the single great cosmic field centre, and each maintains its individual electro-magnetodynamic (commonly called magnetic) field. The repulsions between these fields constitute the force of gravity. Electromagnetic radiation is micro-centrifugal fields in wave formation travelling at top speed in the transmitting (actionic) medium.

The number of atomic weight units in the electronic unit is 546, which thus becomes the basic physical constant. All the atomic weights of the chemical elements are multiples of 546. The actinion carries the force quantum of 12×10^{-30} dyne, the equivalent of the motion of 546 actinions constituting a photon. A photon is pure energy acting on the mass of the transmitting actionic medium. The ultimate force quantum is the dynamion, which on coming in contact with an ultimate mass particle or akinesion at once imparts to it an ultimate energy quantum or kinesion, resulting in an actinion. A photon is 546 kinesions, or the result of 546 liberated dynamions imparting 546 motion units to as many actinions.

Applying the 546-multiple key to the light-velocity problem, it is found that the only number within the limited range of Michelson's (1927) experimental results that is a multiple of the square of 546 is 29979737424, which is also within the Henning and Jaeger corrected range of Rosa and Dorsey's (1907) measurements of the electrostatic unit to the electromagnetic unit ratio in our terms of light velocity. It is Michelson's lower to mean record plus the possible retardation by his mirrors.

FORTHCOMING EVENTS

Saturday, September 11

BRITISH FEDERATION OF BUSINESS AND PROFESSIONAL WOMEN (at the Royal Institution, 21 Albemarle Street, Piccadilly, London, W.1), at 3 p.m.—Dr. Margaret Mead: "Science, Women and the Problem of Power".

Saturday, September 18

BRITISH RHEOLOGIST'S CLUB (at Loughborough College, Loughborough), at 10 a.m.—Discussion on "Rheology in the Hosiery, Leather, Shoe and Allied Trades".

ASSOCIATION FOR SCIENTIFIC PHOTOGRAPHY (at the Middlesex Hospital, London, W.1), at 2.30 p.m.—Discussion on "Clinical Photography".

Saturday, September 18–Sunday, September 19

ASSOCIATION OF SPECIAL LIBRARIES AND INFORMATION BUREAUX (at the Royal Society, Burlington House, Piccadilly, London, W.1).—Eighteenth ASLIB Conference.

Saturday, September 18

10.30 a.m.—Annual General Meeting.
11.30 a.m.—Prof. J. D. Bernal, F.R.S.: "Positive Information Service".
2.0 p.m.—Symposium on "The International Rehabilitation of Special Library Services".

Sunday, September 19

10.30 a.m.—Mr. F. C. Francis: "The British Museum as a Special Library".
11.45 a.m.—Major Irving Newman: "The Organisation of American Photographic Information Services in Great Britain".
2.30 p.m.—Symposium on "The Co-ordination of Abstracting".
5.0 p.m.—"ASLIB: What it is Doing and What it Hopes to Do".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on o before the dates mentioned:

ASSISTANT MASTER TO TEACH ENGINEERING DRAWING in the Middlesbrough Technical School for Boys—The Director of Education, Education Offices, Middlesbrough (September 18).

HEAD OF THE DEPARTMENT OF MATHEMATICS—The Principal, Heriot Watt College, Edinburgh (September 20).

HEADS OF THE DEPARTMENTS OF PHYSIOLOGY, MEDICINE, AND SURGERY—The Bursar, Royal Veterinary College and Hospital, a The University, Reading (October 1).

CHAIR OF NAVAL ARCHITECTURE—The Acting Secretary of Univer sity Court, The University, Glasgow (October 4).

DIRECTOR OF ROBERT GORDON'S TECHNICAL COLLEGE—The Secre tary, Robert Gordon's Technical College, Aberdeen (October 16).

CHIEF CERAMIC RESEARCH CHEMIST—The Ministry of Labour an National Service, Central (Technical and Scientific) Register, Alexandr House, Kingsway, London, W.C.2 (quoting Reference No. O.N.F 1457X).

FUNCTIONAL DEVELOPMENT OF INTERNATIONAL ORGANIZATION

DR. W. E. ALLEE'S proposed address as vice-president and chairman of Section F of the American Association for the Advancement of Science, "Where Angels Fear to Tread : A Contribution from General Sociology to Human Ethics", which has recently appeared in *Science* (**97**, 517–525, June 11, 1943) is of special interest in view of current discussions on the establishment of a working peace system and on the problem of Germany. Cumulative studies in social biology lead Dr. Allee to the conclusion that co-operative forces are biologically more important and vital than their opposite. He insists that the data of biology, if properly understood, are definitely opposed to any social philosophy based primarily on the idea that might makes right in international contacts or in international relations.

Prof. Allee believes that a special obligation rests on biologists to attempt to make sure that mankind does not lose the peace that will follow the present War, in which connexion he urges that those nations will have the best opportunity to win the peace who emerge from the present conflict with their programme of basic research most nearly intact. He suggests that the biological drives towards natural co-operation support the general tenor of a programme in which, first, we should not look forward to punishment for the defeated *peoples*. Secondly, in under-nourished Europe and elsewhere, we should administer relief according to ability to furnish it and to need only, not according to politics or boundaries. Further, we should set up a world organization which will, in principle from the start, and in detail as much as possible, treat victors and vanquished alike. Similarly, if we disarm other nations we must be willing to disarm ourselves, and if we subject any major portion of the world to the control of an international police force, we ourselves should accept a similar control on the same general principles. Again, in regard to curtailment of sovereignty, national governments of powerful peoples, along with those of weak peoples, must discontinue the present policy of determining their own actions in all matters deemed by themselves to lie within the limits of their own sectional interests. All nations alike should be educated for the processes that make for change by the use of peaceful, non-violent techniques. All nations and many classes within nations need, and will continue to need, such education for a long time to come. Finally, Dr. Allee suggests that we should behave towards the defeated peoples from the outset in the way in which Great Britain behaved towards the Boers, and the United States towards the Filipinos, at the turn of the century. Man could, if he chose, focus on his innate drives towards co-operation and attempt to set up a new order based primarily on some such altruistic pattern as this.

The task should be the easier, Dr. Allee considers, because modern biological teaching in these matters resembles many of the social doctrines of the ethical religions, and he urges biologists, as such and as citizens, to try to assist in guiding the existing trend towards a workable world organization along lines which accord with sound biological theory. In such matters the idealist with the long-range view is often the true realist.

The very full study of the problem of Germany which has been issued by the Royal Institute of International Affairs* reaches several conclusions which find support in these views of Dr. Allee. The study is essentially one of the problem of providing for the security of Great Britain in a world in which a dangerously bellicose people like the Germans will continue to exist. It is clear from the start that some compromise between the extremes of force and co-operation must be found: the utter extermination of the Germans or their perpetual enslavement would not be tolerated by the British mind. The Atlantic Charter, in fact, has already committed us to such a compromise, but while the four freedoms are guaranteed to victors and vanquished alike, the vanquished are not to be free to threaten their neighbours again.

A main purpose of the report is to determine at which points of the field each of these two principles of force and co-operation is to prevail. If we are to achieve our purpose, our aims and principles must not be allowed to get in each other's way, and the most valuable part of this study lies in the final section which analyses the prospects of co-operation. This is not to be considered as disparaging to the earlier sections, in which the practical difficulties of disarmament are frankly faced, including the factors which determine the relative strength of Germany and Great Britain which might influence a conflict between the two countries, the possibilities of territorial changes and a new political structure in Europe, the internal government of Germany, economic policy and the control of Germany's war potential. This is a necessary prelude, for the final argument is based on the review of these difficulties and the conclusions, notably that poverty will breed war and that the prevention of German re-armament could be ensured by methods which do not necessarily involve wholesale interference with the capacity of German industry for peace-time production, to which this review leads.

This final section covers much ground that is common to the report on "Education and the United Nations" (see NATURE, August 14, p. 169). Unless the idea of co-operation as a possible and natural state of international relationships lodges in the German mind, displacing the notions of inevitable wars, master and slave races, the rights of the strong and the like, Germany will continue to be a country alongside which it is impossible to live. In rejecting both the extreme views of complete scepticism as to the possibility of changing the German outlook and the over-confidence in the power of education alone to effect great changes, the paper from the Royal Institute of International Affairs is in harmony with Dr. Allee's views. The root of the matter is that a new German outlook, though not impossible, will be necessarily a slow growth, and that, though it can be promoted or retarded by the acts or omissions of foreigners, it must essentially be a spontaneous German development. It will, moreover, be brought about less by precept than by the workings of experience and a new environment.

It is important, therefore, that the policy of the democracies should be such as to favour any genuine attempts by co-operative-minded elements in Germany to establish free institutions. That is one reason why the policy of the Allied Military Government of Occupied Territories (AMGOT) is being watched with such close interest: the other is its importance to the related question of political warfare. While it is impossible at the moment to form any sound idea as to the extent or strength of such co-operative influences in Germany, the Christian Churches may well be found, as this paper suggests, to form a well-tried bridge for an understanding with the West.

Even if the Germans themselves are ready for change, it will not be easy to reciprocate, and on the question of assuming positive responsibility for the whole educational system of Germany the paper is reserved. It lays more stress on the probability of response to American influences, but it recognizes that the German war party will continue to represent Britain as a decadent country. To counter this a vigorous reconstruction policy and programme for Britain, in which social security and educational reform are two essential elements, is important; but it is above all necessary that there should not again be the possibility of Germany attempting to represent defeat in war as victory. The manifest defeat of Germany by force of arms is the first step in the re-education of Germany, even if the lessons of that defeat are not immediately learned.

The real problem here is the time at which vigilant co-operation can be adopted as our policy instead of punishment. However complex may be the reactions of Germany to defeat, we must set ourselves to discover some underlying principle to which the United Nations as well as Germany can subscribe. The four freedoms of President Roosevelt are regarded by this Chatham House paper as providing the most comprehensive and authoritative new definition of a goal of common action. They have the advantage over the Atlantic Charter that they are addressed to the individual and not to the State alone, and are a specific challenge to the German tendency to interpret ideals in a private sense.

Even in good conditions, it will be no easy task to lead the Germans to care greatly for freedom, but that they should do so is the only basis of a tolerable relation with the democratic countries. Freedom they regarded as inefficient, as selfish and as unjust, and offering no convincing object to which faith and idealism could attach themselves. The plunge into Nazism was largely an attempt to escape from these inadequacies and contradictions, and any system which is held out as a possible ground of common international action must meet these needs.

It must first be efficient, and demonstrate that for desirable social ends it knows how to make full use of the scientific and technical possibilities of the new industrial revolution. Secondly, it must be based on an enhanced sense of community, operative not only within but also, in some real sense, outside the frontiers of the State. Thirdly, it must not countenance the maintenance of privilege unconnected with any useful social function. Of one form of this evil the present generation, in Great Britain particularly, is increasingly impatient, and that is educational privilege. Only those educational systems which enable talent, integrity and character, wherever they are to be found, to reach a position of leadership, are in future likely to meet with general approval, and this should not be untrue of Germany. Finally, such a society would be bound to make great calls on the idealism of its members, although it is not within the social order itself that the ultimate springs of moral action arise, and it is ultimately on the ethical view of man as hitherto reflected in the moral attitude of Western civilization that we must depend for the antidote to the dehumanizing influence of efficiency.

* The Problem of Germany: An Interim Report by a Chatham House Group. (Post-war Problems.) Pp. 92. 2s. 6d. net.

While recognizing that security is important, this Chatham House paper puts the main emphasis on the possibility of pursuing common human purposes which transcend national frontiers. It does not indeed suggest that the State will cease to be the basis of international life or that we need no longer reckon with the factors of political ambitions and aggressiveness. On the contrary, it insists on just such a realistic attitude as Einzig in his "Can We Win the Peace ?"; firmness of purpose is essential, and whatever policy of control or disarmament is adopted towards Germany should be one that will command the unfaltering support of Britain, not for two or three but for twenty or thirty years after the end of the present War. The main lesson drawn from the history of disarmament after the War of 1914–18 is not that technical difficulties in preventing Germany from re-arming are insuperable, but that the real danger-point is a weakening of the Allied will to prevent it.

The two chief points emphasized by the study are that military victory may be expected to create, not a better state of affairs, but an opportunity to create a better state of affairs; and secondly, that those who recognize that international life must be lived co-operatively and more in perpetual adjustment and compromise must be content with short views. They can plan within wide limits their internal policy, but internationally they can do little more than decide the general direction in which they desire to go and do their best to ensure that the first steps lead in that direction. Although it is nowhere explicitly mentioned, the Chatham House group seems, in fact, to contemplate the functional development of international organization on which Prof. D. Mitrany insists in his paper, "A Working Peace System"*, also issued by the Royal Institute of International Affairs. It is pointed out, for example, that acceptance of the principle of 'freedom from want' implies as a general aim that the elementary human needs of food and shelter for all should come to be regarded as a first charge on the world's resources. At a higher level of initiative and adventure, the modern readiness to devise bold schemes of national improvement offers to the workers and technicians concerned the stimulus of conscious participation in a great social purpose. This is a matter of great importance in the German situation, both in regard to the unemployment situation and to the imperative necessity of breaking down and correcting the German quasi-monopoly of the higher technical skills over a large part of Europe.

Dr. Mitrany's argument starts from this need for continuous adjustment and settlement which the League of Nations did not, and could not, meet because its members failed to implement Article 19 of the Covenant, providing for the revision of treaties and other matters which might become dangers to peace, and insists on a pragmatic approach in a period of historical transition. He maintains that in place of providing a formal general framework of co-operation in advance, it is more in keeping with the present trend in emphasis from 'rights' to 'services' to organize international government along the lines of specific ends and needs. The sound method of peaceful change, he urges, is to do internationally what it does nationally: to make changes of frontiers unnecessary by making them meaningless through the continuous development of common activities and interests across them. A different complexion would be put on the problem of security if frontier lines became overlaid with a natural growth of common activities and common administrative agencies. Moreover, functional organization offers some prospect of mitigating the difficulties which arise out of State claims to equality by evolving arrangements which show a measurable and acceptable relation between authority and responsibility, relating authority not to sheer power but to the weight of responsibility carried by the several members.

The experience of the technical committees of the League of Nations as well as that of the International Labour Organisation lends support to this view of Dr. Mitrany, and there are precedents in the European Danube Commission which also encourage the view that specific functional arrangements may well tame the principle of State equality. At least we can find here a further reason why the organizations set up specifically to further our immediate war purposes, such as the Combined Production and Resources Board, and the Combined Raw Materials Board, should not be scrapped immediately the War ends, but utilized to serve post-war needs. In particular, the value of such organizations in post-war relief and reconstruction is apparent, and the draft agreement for the establishment of a United Nations Relief and Rehabilitation Administration and the formation as an outcome of the Conference on Food and Agriculture at Hot Springs of an interim commission to plan a Permanent International Organization for Food and Agriculture, parallel with the International Labour Organisation in scope and open to all belligerents and non-belligerents alike, are definite steps in the direction of functional organization.

---

* A Working Peace System: An Argument for the Functional Development of International Organization. (Post-war Problems.) By Prof. D. Mitrany. Pp. 56. 1s. 6d. net.

Discussing the broad lines of functional organization, Dr. Mitrany suggests that public action should only be taken where, when and in so far as the need for common action becomes apparent, and is accepted for the sake of the common good. Only in this way can international organization be well combined with national freedom. Activities should be selected specifically and organized separately, each according to its nature, the conditions under which it has to operate and the needs of the moment. No rigid pattern is required or desirable, and devolution, too, should follow functional lines, functional dimensions determining the appropriate organs.

While each agency could work by itself, the question of wider co-operation must be faced. The co-ordination necessary within the same group of functions, either for technical purposes or for wider functional needs, would be the first stage towards a wide integration. The group concerned with communications illustrates this point. Rail, road and air transport in Europe will obviously require technical co-ordination in such matters as time-tables and connexions, etc., but a wider functional co-ordination will be required to secure the distribution of passenger and freight traffic for the most economic performance. The transition from the co-ordination of several groups of functional agencies to international planning is natural, but overall political authority does not, in Dr. Mitrany's view, appear to be an essential. The general watch over the policies of several joint agencies could well be effected through some such representative body as the Assembly of the League of Nations or the governing body of the International Labour Organisation.

A more fundamental question is that of the structure of the functional controls and the question of representation. Here Dr. Mitrany seizes on the element of professional competence which proved the secret of the success of so many of the League's technical committees, and would make any claim to a share in control depend on a corresponding and evident capacity for performance. On that test smaller States could also qualify, and participants would vary, thus avoiding an exclusive accumulation of influence by a few countries. The same test would govern the extent of the powers of control, and the performance would be practical and measurable, with a periodical balance-sheet, more definite and suitable for examination than the reports to the Mandates Commission, through which the work and policy of each agency could be closely controlled. Dr. Mitrany relies on a personnel which would be largely technical and permanent to develop both a professional pride and a vested interest in good performance, and he adds that not only would the growth of such a service be the best insurance against possible abuses, but also the functional method, by concentrating all attention on a practical public service, is more likely than any other to breed a new conscience in all those concerned with international activities.

Such functional developments will not in themselves create a new system, but, what is much more important, national problems would then appear and be treated for what they are, namely, the local segments of general problems. The system would not be endangered by political or social experiments of one of the participants or even by secession of a member. Authority would derive from the performance of a common task, and be conditioned by it; and while functionalism might lead in time to a federal political system, that would come, if at all, by free organic growth, a natural process of selection and evolution.

The vital questions are, "What are the rightful ends and what are the proper means for achieving those ends ?" Dr. Allee has clearly assisted the formulation of those ends on a basis of scientific as well as social expedience. Dr. Mitrany's powerful plea for functionalism as the means derives important support, as he himself points out, from our present experience with the Combined Raw Materials Board and like agencies, and is also favoured by some of the smaller nations, as Dr. van der Tempel has shown in his recent book ("Keep the Lamps Burning." Hale. 1943. 10*s*. 6*d*.). There can be no doubt as to the value of the organization for relief and reconstruction in Europe in building up a common interest in peace. That may well make a vital contribution in taking certain interests and activities out of the mood of competition and into one of co-operation for the common task. Together these addresses and papers afford impressive evidence that, difficult as is the task before us, it is not insuperable. Given vision, determination and readiness to use the organization, the tools and the technique that lie to our hands, the task of fashioning a world order in which the four freedoms are incorporated and in which Germany herself occupies a fitting place in the European system, may well prove neither so impracticable nor so difficult as victory itself might have appeared when Great Britain stood alone against the Axis Powers in the fateful summer of 1940.

BLUE-PRINTS FOR POST-WAR BRITAIN

Economic Reconstruction

A Study of Post-War Problems. By J. R. Bellerby, assisted by Phyllis Deane, E. Victor Morgan (in Vol. 2), M. Compton and others. Vol. 1: National, Industrial and Regional Planning. Pp. 396. (London: Macmillan and Co., Ltd., 1943.) 21*s*. net.

PROF. BELLERBY is ambitious. In this volume, which is to be followed by a second dealing with international planning, he sets out to provide the blue-prints for a complete system of post-war planning in Great Britain, covering every important aspect of the nation's economic life. Or rather, he presents two different sets of plans, one based on a continuance of private enterprise and the other on a remarkably rapid transition to a nearly complete system of State ownership and collective industrial enterprise. At certain points, notably in the earlier stages, the measures recommended in the alternative plans are largely the same; but the divergence increases very fast after the initial measures designed to deal with the immediate emergency following on the cessation of hostilities. In both plans, it is taken for granted that there must be a profound departure from pre-war policies and assumptions, and that the State must, in one way or another, take the full responsibility for maintaining employment at a satisfactory level, and therewith for raising effective consuming power in steady correspondence with the expansion of the power to produce. It follows that Prof. Bellerby's system of private enterprise involves a very large element of public control, including the effective control not only of the volume of investment, but also of prices (including wages), interest rates and monetary conditions generally, and also the establishment of an assured minimum level of consuming power. In effect, the main difference between the two plans is that in one the State is to undertake directly the conduct of the main industries in accordance with its own co-ordinating economic plan, whereas in the other the execution of the plan, and even a large share in its making, are to be delegated to special organs representative of industry itself.

It is somewhat unfortunate that Prof. Bellerby makes, without anywhere so far as I can see clearly arguing, the assumption that Great Britain will have to choose between these two plans absolutely, and cannot either choose a cross between them, or something different from either. There are, he says, only two economic systems—private enterprise and State enterprise; and between these an absolute choice will have to be made. He says categorically, "From the point of view of planning, a partial change will avail little. The effective choice is between the system of Private Enterprise on the one hand and complete State-ownership on the other." True, later on one discovers that he does not really mean quite this; for he proposes, for some time at any rate, to retain a considerable private sector within the system of State-ownership. But the general scheme of his book is based on the idea of this absolute choice between two systems; and this is where I find his treatment exceedingly unrealistic. For, even if there are in the last resort only two alternative systems (and where, in such a categorization, do such things as the co-operative movement or the London Passenger Transport Board fit in ?), these two systems have many variants, and to say that we must choose between them is not the same thing as saying that we must choose between the particular versions of them presented by Prof. Bellerby. For example, if we choose private enterprise, are we really compelled to have as its accompaniment his peculiar plan for an all-party parliamentary planning conference working side by side with an industrial and economic parliament consisting mainly of employers' and workers' representatives in equal numbers ? Are we compelled to accept his plan for a price-fixing board which is to have complete final control over wages in all industries, as well as over prices ? Or, if we opt for State-ownership, must we really take over 75 per cent of the national productive activity of the country in a few gigantic swallows spread over but a very few years ?

This is surely a false dilemma. It may be true that we shall have to make up our minds whether we wish the driving force in post-war economic policy to be socialistic or capitalistic, and to get ourselves a Government in accordance with our general preference. But it does not at all follow that the Government we get must pursue a 100 per cent policy of either Socialism or Capitalism. If Prof. Bellerby were contemplating the possibility of a socialist system applied as the outcome of a revolution *à la Russe*, one horn of his dilemma might exist; but he explicitly excludes such a situation from his subject, and assumes a post-war economic order that is to be built up by constitutional means. The result is that he is apt to impale himself on the horns of his own unusual dilemma. It is nonsense to suggest that a plan could not work at all unless it had precisely the composition postulated for one or other of his two alternatives.

It is a pity that Prof. Bellerby has marred the shape of his book in this way; for there is in it a great deal that is good. He is much more prepared than I am to trust representative bodies of employers and workers to make plans which will be free from restrictive taint and will be constructed solely with a view to the common benefit of the people; and he seems to me to be unrealistic in his handling of the extremely complex and difficult problem of price-control, and still more in his proposal to make wage-control a secondary function of his price-controlling body. As against this, there is much that is excellent in his discussion of State planning policies and methods, in his account of the problems and prospects of each of the leading industries, and in his attempt to distinguish between the probable stages of economic emergence from war to peace. His discussion of these matters involves too much detail to lend itself to summary; and it is to be hoped that what I have said earlier by way of criticism will not deter any reader from studying it.

The fundamental problem of economic planning, as Prof. Bellerby envisages it, is the maintenance of an adequate level of consuming power. He accepts completely the view that the radical disease of capitalism in the pre-war world was its tendency to generate crises of under-consumption. Indeed, he states this position in terms that are a great deal nearer Hobson than Keynes, and lays proportionately large stress on measures for the maintenance and increase of consuming power, both temporarily in the emergencies that may be expected to arise during the successive phases of reconstruction, and also permanently. He wants, as immediate post-war measures designed to be permanent, both family allowances and a guaranteed minimum standard of income : he lays stress on the beneficent effects to be looked for from the repayment, at the right times, of service gratuities, post-war credits, refunds of excess profits tax, and so on. But he goes further than this, and contemplates the actual creation of purchasing power by way of all-round gifts to consumers as one of the means that it may be desirable to use in combating post-war depression. I am glad to see that, in connexion with these proposals, he recognizes the imperative necessity of avoiding, during the critical period of reconstruction, any binding stabilization of the pound in relation to gold or the dollar, though he does appear to contemplate that such stabilization may come later, as the accompaniment of an agreement to follow common expansionist policies in the conduct of economic affairs.

In general, Prof. Bellerby has written an interesting, and often suggestive, book, but has written it on a bad plan. Some of his dogmatism is due to the attempt to crowd in too much and to cover more ground than one man can cover in one book, however richly he may be endowed with research assistants. But some of it is due to a mistaken striving after clarity, in face of possibilities so varying that he is tempted to exclude most of them, and to choose just those which fit in best with his general plan. He is at his worst when he is discussing his second alternative—State-ownership; further, he makes all sorts of unwarrantable assumptions about the way in which industries would have to be nationalized, and the forms which compensation (or the absence of it) would necessarily take. His discussion of private enterprise is much better, because there he is dealing with something that exists, and has to begin by taking it as it is, and not by constructing an unrealistic model and then treating it as if it were the only possible variant. If this review is less favourable than the book deserves, it is because this state of unrealistic formalism in its author has annoyed me, and caused me to do less than justice to the particular things he has done well.

WEED CONTROL

Weed Control

A Textbook and Manual. By Prof. Wilfred W. Robbins, Prof. Alden S. Crafts and Richard N. Raynor. (McGraw-Hill Publications in the Agricultural Sciences.) Pp. xi+543. (New York and London: McGraw-Hill Book Co., Inc., 1942.) 35*s*.

THE problem of weeds and their control or eradication is one which increases in importance with modern advances in agricultural practice. On land giving low returns, due to poor quality of the soil, poor cultivation or other factors, it may be uneconomic to adopt any intensive methods of weed control. On well-cultivated land, in good heart, and bearing heavy crops, it is justifiable and often profitable to expend considerable time and money in combating weeds in order to bring the reduction of crop due to competition to the lowest possible level. Much experimental work has been done and much written on the subject, and Messrs. Robbins, Crafts and Raynor have rendered a great service by gathering into one volume a comprehensive survey of this field of activity.

The rapidity with which weeds spread from one area to another emphasizes the need for a primary method of control, involving rigid inspection of imported seeds and prompt dealing with initial infestations of bad weeds. The worst pests in many countries, such as blackberry, Russian thistle, creeping thistle and morning glory owe their unenviable position to neglect of this elementary precaution. Furthermore, changes in methods of cultivation may cause native species to behave as weeds.

The harm caused by weeds is due not only to their demands upon the limited amounts of food and water available in the soil, the water requirements of bad weeds often being greater than that of the crops. Heavy expenses and monetary loss also are involved in control and eradication, in seed cleaning, clearing ditches and in the reduction of the market value of crops. The quality of milk, grain, hair and wool is often reduced, and certain weeds also act as alternative hosts for various crop pests.

Control and eradication need to be distinguished, as the latter is seldom economically possible, except in such cases as dodder. The life-history of weeds is closely related to effective methods of control, and for large-scale work very special methods have been evolved, as flooding by water, heat treatment by flame throwers and steam boxes, and paper mulch in areas of very rapid growth. There is, however, no universal panacea for killing weeds, and, to quote the authors, "general recommendations must be interpreted in the light of the specific situation, amended to meet the requirements imposed and tempered with judgment based on local experience".

On arable land the time-honoured method of weed control by careful cultivation is still often the most economical procedure, but great strides have recently been made with chemical agents. These may act in various ways: as herbicides killing by contact with the leaves or by being translocated through the plant tissues, or as soil sterilizers preventing the growth of plants over varying periods of time. Some chemicals, as sodium arsenite, are non-selective and kill all vegetation by contact; others are selective, killing weeds but sparing crops of certain types, as occurs with charlock among cereals. This group of weed killers includes highly soluble fertilizers and toxic compounds which are reduced in toxicity by contact with soil.

Translocated sprays, the physiological action of which is discussed, pass downwards through the tissues, killing as they go. Arsenical sprays and sodium chlorate fall into this group. The same weed killer can be used in various ways, according to the rate of application and the environmental and soil conditions.

Detailed accounts are given of the more important weed killers with full reference to the work of many investigators, a bibliography being appended to each chapter. For convenience of reference these authors are gathered into a general index, though this does not appear to be complete, as such an important investigator as Korsmo fails to appear therein, although adequate reference is made to his work in the text.

Weed control on special areas as railroads, paths, etc., is effected by soil sterilants, among which sodium arsenite stands almost alone as regards permanence. All others are more or less temporary in nature, the type of soil and environmental conditions affecting their action considerably.

Weed control by chemical means entails of necessity special machinery, much of which is effectively illustrated. Consideration is also given to various special problems, as the weeds on grassland and on uncropped areas, control of dodder, and stump- and tree-killing, the latter sometimes being dealt with by injection of poison. Certain weeds receive special attention; for hoary cress, morning glory, sheep sorrel, Russian thistle, and puncture vine, among others, are so dominant where they occur that they constitute major problems. In the appendix various useful tables and lists are given, including an estimate of the number of seeds produced by various weeds, and examples of native species in various areas which have now usurped the role of weeds.

The authors are to be congratulated on producing a book which will be of great value to all who deal with the land, and which should stimulate experimental research on practical and economic methods of weed control.

WINIFRED E. BRENCHLEY.

RACE, CLASS AND MATING IN THE EVOLUTION OF MAN*

By DR. C. D. DARLINGTON, F.R.S.

The Background

QUESTIONS of race in man have been the subject of increasing dispute for the last hundred years. Most of the positive opinions that have been advanced owe little to our recent knowledge of heredity, but they show the background on which we have to work in applying this knowledge. Our starting point has to be the primitive or Old Testament view. It was expressed by Archbishop Trench when he gave the opinion that the savage "is a dead withered leaf, torn violently away from the great trunk of humanity, and with no more power to produce anything nobler than himself out of himself, than that dead withered leaf to unfold itself into the oak of the forest"[1]. On the other side Darwin opposes to this pessimism the more hopeful view that "all the races of man . . . are descended from a single primitive stock" and have come to differ in heredity during a continuing process of improvement[2].

These opinions differ in the direction of change, backwards or forwards, but they agree that there has been change. Powerful hereditary differences both in mind and body distinguish the races of man. A third view, which springs from the New Testament and also owes something to Rousseau and Marx, emphasizes, both for race and class, the importance of differences in the environment rather than in heredity. Such a cleavage of ideas as to the genetic evaluation of human races is assisted by the facts recognized by Darwin. "If we reflect on the weighty arguments," he writes, "for raising the races of man to the dignity of species and the insuperable difficulties on the other side, in defining them, the term 'sub-species' might here be used with much propriety. But from long habit the term 'race' will perhaps always be employed"[2].

To-day the "weighty arguments" and the "insuperable difficulties" are still at war. On one side stand those who, following Gobineau, assert that modern peoples spring from hypothetical pure races, from one of which, happily superior to the rest, they themselves are descended without contamination. Further, they hold that races described as Nordic and Mediterranean, and even their mixtures, can be recognized by the forms and features of individuals[3]. Even, by a further stretch of theory, they take language as an independent and sufficient criterion of race, and it is from this simple view that the "ethnographical" maps which appear in our atlases take their title. At the same time, on the other side are those who say that every population "includes many types and their various combinations" and therefore "the word *race* should be banished, and the descriptive and non-committal term *ethnic group* should be substituted"[4]; and further, "the so-called racial explanation of differences in human performance and achievement is either an ineptitude or a fraud"[5]. Again, by a stretch of this theory, it is held that primitive peoples can, by prolonged subjection to the benefits of European rule, be brought to develop a culture comparable with our own, when they will be, as it is said, ripe for self-government.

Both these lines of argument are now being politically applied. It is therefore worth our while to try to form an opinion of their scientific value. Such an opinion can, I believe, be reached on the basis of the postulates, and on the analogy of the conclusions, of experimental genetics.

Mating Systems

We must begin, following the example of Darwin, with something we understand better than man. namely, the breeds and races of domesticated plants and animals. If a plant is regularly self-fertilized—a rare condition—we can agree that all the descendants of one plant, or of a group of indistinguishable plants, will, as a rule, conveniently constitute a race or variety. Even so, if they are divided into groups that undergo mutations and are differently selected, the groups will become separable, and sometimes are separated, as distinct races.

When we turn to cross-fertilized plants and animals we find quite another state of things. It is now a question, not of one parent, but of the group from which any individual may take its two parents, and from which all individuals will later take their ancestors. The mating group and the group of common ancestors are the same type of unit. In no such group will all the individuals be alike, and they may be highly diverse. To what then does the group owe any unitary character it may possess ? It owes its character to what we may call its chromosome pool. It is a property of germ-cell formation that half the chromosomes of the parent are rejected in the formation of each germ-cell. In a stable population therefore, where two parents have two offspring, one quarter of their chromosomes are lost to the chromosome pool in the next generation and one quarter are doubled in frequency; only a half reappear once. By mere chance the pool suffers regrouping and by mere chance two separate pools will be differently changed, and, if they are small, rapidly changed[6].

There is something more than chance, however, at work. Different groups are inevitably differentiated by selection whether natural or artificial. The original and subsisting function of sexual reproduction is to expose to selection all the gene-combinations it can produce at every level of their activity and in the greatest possible range of environments. The conditions of survival and reproduction of the individuals produced by the recombinations of genes and chromosomes are different in different countries, climates and ways of life. Selection is continually changing the character of the chromosome pool by differences of survival and of fertility. Every couple will not have two offspring; and most of the genes concerned are individually invisible in their effects. Furthermore, selection is throwing away, not only unsuitable genes, but also unsuitable combinations of genes, and so balancing the genes contained in the chromosomes against all the others with which recombination from the pool brings them into relationship. This internal selection is producing what Mather calls a "relational balance" which is characteristic of the particular mating group[7]. Thus at three levels, the environmental, the genetic, and the jointly genetic and environmental, cultural, level any mating group has a unified selective response which differentiates it from all others.

With two inbred groups, the cross-breeding of which is prevented, the point at which we shall begin to refer to them as races is then a question of *ad hoc* convenience. We can merely say that that point will be reached more quickly if the groups are smaller; if the original differences between them, and the heterogeneity within them, are greater; if their mutation-rates are higher; if their selection is more rigorous or more divergent.

---

* Substance of an address given to the Association of Scientific Workers in Cambridge on July 16.

In our domesticated races we are accustomed to use as our index of pure-breeding certain clear genetic differences, the 'points' of the breed. These are determined by major or 'marker' genes. We cannot attend so strictly to the minor or 'polygenes'. Artificial cross-fertilized breeds are therefore always more heterogeneous than they seem. Marker genes are also used by the classifiers of wild plants and animals. They are not, however, the most important agents in separating natural groups in animals or man. This is recognized by the use of geographical and historical criteria in addition to morphological ones. We now know that natural groups have often become intersterile without any difference having been noticed by the morphologist; and if invisible polygenic differences separate races their internal homogeneity due to their inbreeding must also be invisible. Natural races are, therefore, more homogeneous internally than they seem, by comparison with artificial breeds. Thus convergence as well as divergence is partly cryptic, and so far as it is cryptic its only measure, apart from experiment, is the breeding history of the group.

Group Limitation in Man

It is our business to find out how this group effect has worked in the history of mankind. Man is derived from a group, at the beginning of his independent history, of ten, or perhaps a hundred, thousand ancestors. These common ancestors were genetically diverse, perhaps as diverse as any living men. Their progeny have continually expanded in numbers, and these numbers alone have set the *genetical* limit to the inter-breeding group in man. Within this expanding population, however, there have been *physical* limits to the effective breeding groups and these have not always expanded. Mobility has depended on geography and on civilization, either of which may help or hinder it. Navigation helps, agriculture hinders. Finally, there have been *social* limits to the mating groups which restrict the choice of mate to a fraction of those who are physically accessible. They depend on man's intellectual discrimination, which itself has developed with his cultural evolution. They have, therefore, been applied with increasing rigour as the density of human population has increased; and, though cultural in origin, in effect they are always genetic as well, since culturally separated communities must always become genetically distinct.

When the cultural barrier arises from the physical limitation we have the characteristic origin of race. When it arises from a social differentiation we have the origin of class. When the two are combined and stabilized we get the formal climax of caste in India.

How large in effect are the mating groups into which man is divided? Keith[8] has surveyed the action of 'tribal instincts' in restricting their size in primitive peoples. The invisible divisions of civilization can be measured in other ways. One is from the frequencies of the blood group genes[9,10]. The distinctness of Jewish and Gipsy minorities from the neighbouring majorities shows the strictness of their previous inbreeding. Prof. Fisher tells me that, in rural Ulster, groups with English and Scottish surnames still remain distinct; with a minor religious distinction scarcely any intermixture has occurred during ten generations. Church records of Ulster communities in North Carolina show that the same endogamous habits have been carried across the Atlantic[11]. In the same way the frequency of conditions due to recessive genes can be used to establish the separation of groups. If deaf mutes are 4½ times as frequent among Jews as among Gentiles in Berlin, the two groups must be effectively separate breeding units[12].

Again, Dahlberg has inferred the average size of the group among which mates are chosen from the frequency of cousin marriage[13]. This frequency has changed in Bavaria, for example, as though the size of the group had increased during the last fifty years from 2,000 to 5,000. Increased mobility has been breaking up the agricultural breeding system.

Other methods of measuring the mating system and its effects, using the frequency of X-chromosome genes and of heterozygotes, will doubtless be used in the future[12,13,14]. But we can already infer in these different ways that the mating group among civilized peoples, although less stable, is not always larger than among primitive peoples and is smaller than is usually believed by the individuals concerned.

Adaptation of Classes

A part of the subdivision of a race into smaller mating groups is inherently adaptive. The closer social intercourse within groups following the same trade favours the mating of similarly adapted individuals. This effect is reinforced by assortative mating. As Pearson found, there is correlation between the heights of husbands and wives. Like mates with like. All over the world, not only in India, fishermen, cotton-workers, coal-miners and peasants are inbred groups. Moreover, groups lose those individuals who are least suited to them. Thus selection will exaggerate itself. First a man selects his mode of life and then his mode of life selects him. The saying that it takes three generations to make a cotton spinner may well reflect this process. Nor can we doubt the advantage that has come to the world from the assortative mating of musicians. These are processes which will continue to be refined by each new development of human culture so long as individuals are free to choose their mates.

In monogamous societies based on hereditary wealth, economic differences cut across adaptive differences and establish a still finer subdivision of mating groups. This effect will always be strongest in the layers constituting the governing class. This class is of paramount importance in determining the real and apparent 'national character' and hence in controlling racial evolution. In its origin, like other groups, a governing class must in a sense be adaptive, that is to say, selected for its capacity to govern under the conditions prevailing at the time. Is it capable of maintaining its adaptability? The answer is that there are two main conditions operating to prevent it doing so.

The first is that groups within it are not highly inbred and specialized for their function. Among eminent churchmen (the most inbred profession in England) for the last fifty years only 25 per cent have been sons of churchmen, and the proportion who have married the daughters of churchmen is now even lower than that ("Who's Who", 1890–1940). From the mixture that is going on, segregation of unsuitable types is therefore likely to be more frequent than in the working classes. But the inheritance of wealth (or power) gives a governing class the means, which it is bound to use, of releasing itself from selection pressure, of preventing its members taking their adaptive level. This effect is partly a cultural effect of family life, but it can be assisted by the development of such special educational barriers between classes as we find in England.

The second condition lies in the mechanism of social diffusion by which governing classes may be reinforced and their deterioration avoided. On one hand, diffusion between classes may be prevented. Then, not only are human individuals wasted but also genetic materials, useful to the race, are apt to be thrown away, since they are tested in the wrong environment. For a while, of course, such materials may accumulate until changes such as the English, French, or Russian Revolutions occur to make use of them. If, however, they are to be stored, as in India, for thirty or forty generations, these elements will be lost before they can be used. The social tension will be released and the system internally stabilized. The economic and professional castes of India temporarily broken by Buddhism and loosened by the Mohammedan invasion have been given by British rule an organic rigidity to which every process of ordered government, even the Census, contributes a stabilizing effect[15].

On the other hand, where social promotion occurs, at first sight it might appear that social merit must always be its chief agent. But just as a governing class in its origin is always mixed, so it will be in its reinforcement. To this process Fisher[16] ascribes the decay of governing classes and in turn the decay of the empires they govern. He suggests that social promotion of men is favoured by the reduced fertility of their parents, which has been shown to be heritable. This effect will be all the more important for exaggerating itself. But it is only a part of the story. The social promotion of women will always be based on qualities of a different kind from those favoured in the promotion of men and often conflicting with them. Its effect will be predominant where the governing class is legitimately polygamous. We may, therefore, see in the excessive fertility of sultans and emirs a process contributing to the rapid decay of Islamic cultures.

Thus class division combined with diffusion are necessary for the efficient utilization of the race where the differentiation of the culture is stable; but the conditions of diffusion, unless suitably controlled, may make it little better than no diffusion at all.

Conflict of Systems

If mankind had long been broken up into genetically isolated fragments it would at once be obvious to us that race made culture and language. Any group, however heterogeneous, would have to be held genetically responsible for its aggregate cultural activities. Now both races and culture are continually being mixed, but culture is a more important obstacle to this mixing than race. Hence the relationship becomes reciprocal. Culture and language often make race just as much as race makes culture and language. It is this argument, combining genetic premises with a dialectical change, which has hitherto defeated historians and philosophers.

When languages are mixed or transferred the process is always selective. In Burma social advancement is often the incentive and tribes "change their language almost as often as they change their clothes"[15]. The same principle applies in the West. Owing to the dominant cultural influences of certain Western languages, English, French, German, Spanish, Swedish, Russian, Turkish, Persian, minor language and dialect groups have at various times become socially and culturally depressed. Where the depressed group has held on to its language in spite of this, it has by social diffusion lost genetically useful elements to the dominant group. In recent times we have seen the resurrection of such depressed and genetically extracted classes as nations, and the artificial result has sometimes been disappointing. A similar genetical extraction and depression has commonly benefited the town at the expense of the country and the capital at the expense of the provinces. Again, where a caste system is fixed, as in India, this extraction is prevented to the common disadvantage.

When conquest breaks down a mating barrier, and races fuse, outbreeding momentarily succeeds inbreeding with results which historians again have found hard to explain. The most instructive of these changes is that accompanying the expansion of Islam, for here the same experiment was repeated, extending in time over a thousand years, and in place from Marakesh to Delhi. The choice Islam offered to the vanquished with varying emphasis was a simple one: exogamy or death. The result was nearly always the same. New genetic combinations were able to take advantage of new cultural combinations and a striking cultural development took place, although limited for the reasons we saw to seven or eight generations. This effect was due to the breakdown of class as well as race barriers assisted by polygamy. The conversion to Christianity, on the other hand, had no such striking cultural consequences, because it did not destroy the existing mating barriers established by class or by race.

Polygamy thus affects both class structure and sexual selection; and sexual selection is biased by changing social conditions. The two sexes must always be complementary in reproductive function but otherwise their adaptations are, genetically at least, as different as those of two closely related species. Karl Pearson[17] showed how the average cranial capacity of different races differed and how the proportions of male to female also differed. His summary led him to the conclusion that in the older civilizations which were closer to a matriarchal stage of development, women's cranial capacity was relatively larger than in modern civilizations. Whether or not this inference is sound we cannot help assuming that human history has been a process of intellectual specialization of the two sexes which for the reasons we have seen will have led to different results in different races and classes.

The historic change from matrilinear to patrilinear inheritance has also led to important conflicts. In all groups of mankind exogamy rules have probably existed at one time. Marriage has been forbidden within certain degrees of relationship, real or imaginary. The system has reached its highest development in the sparsest and therefore most inbred communities, as in Australia[18,19].

The exogamy rules often break down. They do so especially when the inheritance of property develops during an unresolved conflict between matrilinear and patrilinear inheritance. The result is an instructive experiment. In the Ptolemies, successful incest began after a half-cousin marriage. In the whole line of thirteen, eight had full brother-sister marriages, but only three were fruitful. No two of these were in successive generations. The legitimate inbred line died out and Cleopatra's mother is unknown[20]. Similarly in Peru only one of the royal Incas is known to have been the issue of a brother-sister marriage. In neither case was there any continuous incest[21].

Successful and regular incest, on the other hand, has frequently been maintained by half-sister marriage, for example, in the Eighteenth Dynasty in Egypt[20]. Such marriage was common also in ancient Athens and among the Mongols and it occurred in Ur and in the royal house of Siam. The practice is no doubt helped by half-sisters being very numerous and also by the action of the matrilinear incest taboo. The evidence of experimental breeding in turn makes sense of this taboo. Only in five generations of self-fertilization and in ten of brother-sister mating will sterility usually wipe out the inbred stock. The effect will be most drastic when inbreeding is suddenly introduced in an outbred stock, and the inbreeding must be continuous to be cumulative. The exogamy rules of man like most moral laws seem, therefore, to have been derived by an extreme extrapolation. Incest is directly dangerous to the progeny only under special conditions which have nothing to do with those governing the indirect effects of inbreeding on a whole group.

The group effect of inbreeding is that it gives homogeneity, predictability of offspring from parent, rapid adaptation, easy transmission of culture, sometimes too easy, and hence potential stability of culture. It is a conservative agent and it conserves itself best in the most conservative peasant communities. It opposes initiative. It reduces conflict, sometimes disastrously. If applied to specialized classes it conserves their differences and increases their fitness. In India the endogamous caste system has preserved a store of variation which, if released by free crossing or recombination, might well enable us to reconstruct the whole genetic range of mankind.

On the other hand, inbreeding, while increasing temporary fitness, reduces flexibility. It reduces the means of acquiring fitness to new conditions. The Andaman Islanders steadily decreased in number from 4,800 in 1858 to 460 in 1931[15]. This is said to be due to the deleterious effect, either of inbreeding, or of the contact of civilization with a primitive people. It would be more accurate to say that it was due to a homogeneous race being confronted with conditions to which it was not adapted. Homogeneity provides the optimum condition for epidemic. Heterogeneity permits selective survival and recovery.

This advantage of heterogeneity merely shows in a special way how inbreeding frustrates the long-term function of sexual reproduction, the recombination of genetic differences, recombination which cannot take effect without the combination of these differences by outbreeding.

The long-term function of outbreeding has moreover come to imply a short-term advantage. Species become adapted to outbreeding and the adaptation, as we saw in regard to incest, cannot be overridden without risk. This adaptation has been explained in general polygenic terms by Mather[7]. His explanation is all the easier to apply owing to the probable importance of super-genic differences arising through inversions of groups of genes. These are more likely to favour the heterozygote than are single gene systems since they cannot be broken up by recombination in the heterozygote. The equilibria of blood group and taste genes which seem to have persisted in man since before his separation from the apes[22] suggest such a favouring of heterozygotes.

Hybrid vigour might be expected to be shown in these circumstances. Dahlberg[23] attributes the increase of average height of recruits in Sweden by 9 cm. to the increased outbreeding following increased mobility. The change is steady over a hundred years and cannot, therefore, be due entirely to improved nutrition. We are accustomed to regard such a change, which is noticeable also in England, as advantageous, and that may be so. But if the previous range of heights was an optimum, secured by adaptation to conditions which have not changed, we must now be too tall. Thus there is a conflict between the advantages and the disadvantages of outbreeding at both genotypic and phenotypic levels and as between the short view and the long one.

How then is this conflict to be resolved? In general the combination of inbreeding and outbreeding in parallel rather than in sequence gives the greatest efficiency in the utilization and selection of the available variation of mankind and, consequently, the most rapid evolution. A subdivision of mankind into races and classes is, therefore, highly advantageous provided that we can assure its instability. This seems to be no insuperable difficulty at present. The rapidity of differential population changes, the increase of mobility, the changes of methods of production, and the technical requirements of government, have upset the stability of races and classes as well as the adaptation which partly justified that stability. In these circumstances the 'young' peoples newly derived from a mixing of races or of classes have obvious advantages over the most permeable of stable societies yet known. Outbreeding for the moment is in the ascendant because cultural evolution is increasing its pace; and this again is a reciprocal and therefore self-exaggerating effect.

Conclusion

Man's intellectual and cultural evolution has led not to an absence of the races found in other species but merely to a special character in these races, due we may say to a special combination of artificial and natural selection. He uses a cultural and intellectual discrimination in the subdivision of his mating groups which must artificially accelerate his evolution. His habits of migration and conquest, on the other hand, continually constitute new groups of hybrid origin. These must therefore be, for most of their lives, groups, not of decreasing, but of increasing homogeneity. The common posterity, rather than the common ancestry, is what matters in human races and classes. Moreover, these groups are not classified by marker genes. For all these reasons human races and classes are more homogeneous than they seem; animal breeds, by contrast, less so.

We must, therefore, regard those who would have us shut our eyes to the genetic differences between races and classes, lest the recognition of unlikeness should generate antagonism, as offering us the counsel of timidity and escape. Let us rather consider that all the races and classes of men, however distinct, and usefully distinct, are likely in the end to have their posterity in common and to the common advantage; and that this posterity will still be classified and subdivided. Meanwhile, let us use the methods at our disposal for evaluating the different genetical and cultural prospects of different races and classes and systems of mating. In doing so we shall recognize the reciprocal connexions that exist between changes in the mating system, the economic system and the political system. For in changing one we are likely to change all three, and the systems which are functionally the most advantageous have a prospect of being eugenically the most desirable.

A MIOCENE ANTHROPOID MANDIBLE FROM RUSINGA, KENYA

By DR. L. S. B. LEAKEY
Coryndon Museum, Nairobi

IN September 1942, during a brief period of leave from my war-time duties, I was able to revisit the Miocene fossil beds on Rusinga Island in the entrance to the Kavirondo Gulf of Lake Victoria. During my stay on the island, I had the good fortune to discover a nearly complete anthropoid mandible *in situ*. This was removed in its matrix to the Coryndon Museum, Nairobi, and there developed.

The Rusinga Miocene fossil beds were studied by my third East African Archæological Expedition in 1931–32, and again in my fourth expedition in 1934–35. On both occasions collections of fossils were made which included anthropoid material, and on the second occasion, in 1935, the expedition geologist, Dr. P. E. Kent, made a special study of the fossil beds from the stratigraphical point of view, and of their relation to other Miocene beds in Kenya.

The new mandible now discovered in these Rusinga Miocene beds is by far the most complete anthropoid specimen yet found in Kenya, and is of special importance. It has the whole of the symphyseal area preserved intact as well as the left condyle and coronoid. A detailed study of the above specimen as well as many other less complete Miocene anthropoid fossils from Kenya has now been prepared by Dr. McInnes[1]. The object of the present communication is to give a preliminary account of certain features of the new fossil, so as to enable those who are interested to order reprints of the more detailed paper.

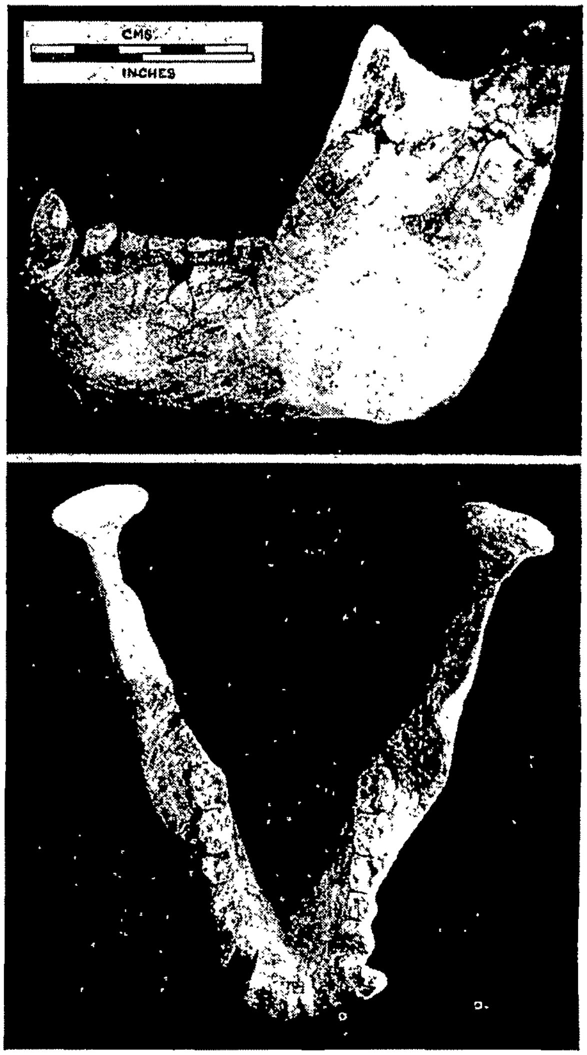
The characters which appear to be of special importance are:

(1) There is no simian shelf such as is seen in modern apes and also in Dryopithecus. The most backward point of the symphysis is in the region of the genial tubercles as in man. From this point the symphysis bends forward again much as in man, instead of having a backward projection from a genial pit as in the great apes.

(2) The premolars are much reduced in size.

(3) The first and second molars are wider posteriorly (distally) than anteriorly (proximally). This feature is associated with a shortening of the molar premolar series, indicative of a reduction of the muzzle-length and probably a more vertical face than in living great apes.

(4) The ascending ramus is relatively high and



MIOCENE ANTHROPOID MANDIBLE FROM KENYA.

wide compared with the size of the corpus and the area of the chewing surface.

(5) The molar-premolar series are remarkably convergent anteriorly as in man, and not parallel or convergent posteriorly as is usual in the great apes.

(6) The form of the condylar process approximates more to that seen in man than to that in the living apes. Unfortunately, this part of the mandible is unknown in any other fossil ape.

(7) Viewed from the front, the mandible has a certain general resemblance to the human form.

(8) The flat wear of the molars is reminiscent of that seen in Eoanthropus and man rather than the type of wear seen in the great apes. On the other hand, the canine is large. The third molar exhibits the typical Dryopithecus pattern of the cusps, and the premolars, though reduced in size, are more anthropoid than human in character.

This new mandible is assigned to the genus Proconsul originally described by Dr. A. T. Hopwood from fragmentary material from Koru, Kenya, but it does not seem to bear out his interpretation that "the genus is ancestral to the chimpanzee", but rather supports and gives added point to the view expressed by Drs. Gregory and Hellman, that Proconsul stands "near to the common ape-man stem".

I would like to express my thanks for the comments sent to me by Sir Arthur Keith, Prof. Le Gros Clark and Dr. W. K. Gregory as a result of notes and photographs sent to them soon after the discovery was made.

CONFERENCE ON THE FUTURE OF ARCHÆOLOGY

By KATHLEEN M. KENYON

Acting Director, Institute of Archæology, University of London

AT the present time, the thoughts of many people are turning to the problems of the post-war period. Many of these problems are material and in the economic sphere, but equally important are those in the cultural and educational sphere. Some archæologists have been considering in what way and by what means archæology is going to make its contribution to the post-war period, and during August 6–8 a conference on the Future of Archæology was held at the Institute of Archæology of the University of London, at which some 280 people were present, including most of the leading archæologists at present in the country.

The dominant theme was that archæology, as Mr. W. J. Varley expressed it, was no longer the pursuit of a very recondite erudition by a select few in a quiet temple dedicated to no other purpose. It was a study which could clothe the past with reality, through which man can achieve what is essential if he is to survive, a sense of community with all other men in the world of space. Dr. Grahame Clark, who opened the conference with a paper on the "Contribution of Archæology to the Post-War World", put the claim of archæology to be of value to everyone, in his statement that it not only gave to old and young alike an understanding of the birth and growth of culture in their own lands, but it also provided a basis of common understanding between men of all nations, since the early history of mankind in the Palæolithic period, for example, formed a common heritage of all men.

Prof. V. G. Childe, in a stimulating paper on the "Unity of Archæology", stressed again this same point. The different branches of archæology had grown up by varied means. Classical archæology, due to its antiquarian ancestry, had developed from a search for monuments, coins and inscriptions. Mesopotamian archæology was originally interested almost entirely in tablets and sculptures, while prehistoric archæology, owing to the lack in this sphere of more spectacular relics, was compelled to devote attention to everyday objects, and the way of life of the common man. Gradually, however, all branches were coalescing and making as their common aim that of recovering and reviving the life of societies of the past from their concrete remains, and to do this all branches were borrowing methods from the others. A unity of approach was highly important, since archæology alone can tell how and in what directions humankind has progressed. Written history is too brief, and only archæology can survey men and their achievements over half a million years in every corner of the globe.

The problem next in importance to be discussed was how archæology, granted thus to be important to all, could be placed before the public in an interesting and palatable form. In a session devoted to "Archæology and Education", the different ways that the subject could be introduced into elementary, secondary, university and adult education were discussed, and the matter came in again in the session on "Museums and the Public". Archæology, through reconstruction and visible remains, can make local history live both to children and adults, and the child who could see actual Roman leather shoes, and the British workman who could carry through voluntarily an arduous excavation in order to see what sort of a job his Iron Age ancestor had made of digging a rock-cut ditch, were gaining something which no amount of lessons or lectures could give. Many illustrations were given of the widespread interest there is in the concrete history of the past. To meet this, archæologists must be prepared to popularize their science. All teachers of history, geography and art should have a grounding in archæology, and something should also be done to bring home to men of science that life is not all atoms and formulæ, but that some kind of historical knowledge or understanding is essential to make them educated men and women.

Other sessions were devoted to the actual problems, both archæological and of organization, of the future. Speakers outlined the problems needing attention in the different fields. Both Britain and the Near and Middle East were covered by a number of papers, and detailed suggestions of needs for the different countries were made, while during the discussions, emphasis was laid on the fact that areas such as Central Asia, the Far East and South America should not be neglected. A very special problem was set by the opportunities given by war damage for the examination, before reconstruction, of sites both in Britain and the Mediterranean area, and adequate provision for this must be made. The need for planning was continually referred to, but Mr. J. N. L. Myres made the very important point that planning must be elastic and must neither curb individual initiative nor regiment research.

In all the addresses there kept recurring the view that, in the conditions to be expected in the post-war period, archæology would be financially in a difficult position. Though some speakers felt that security was undesirable, and that archæologists were the more devoted from having to stump the country raising funds, as did Sir Flinders Petrie, the general consensus of opinion was that unless some reasonable prospect of a livelihood was held out many promising students would be lost. The growing difficulties of archæological societies were pointed out by both Prof. Alan Gardiner in his comparison of the palmy days of the Egypt Exploration Society at the end of the last century with its present state, and by Mr. H. St. George Gray in his survey of the responsibilities and commitments of the local British societies. Many felt that some form of State assistance was both justifiable and necessary. Others, however, feared that any form of State assistance would involve State control, which might hamper the freedom of research. A solution advocated by Mr. Grimes, and supported by many, was that in connexion with some State organization co-ordinating the different bodies at present concerned with State archæology, there should be some form of grants, made through a responsible archæological body, which would ensure that research as such was adequately endowed, but free of officialdom. Sir Leonard Woolley put forward an eloquent plea for State support for British schools of archæology abroad, with the suggestion that these should be sponsored by the British Council. Other speakers supported his plea for strong British schools, though they deprecated any suspicion that archæology should be used as a means of official dissemination of British culture. Good relations would result from them, particularly if they were open to the nationals of the country in which they were established, but they would be a by-product of the main end, the furtherance of knowledge.

The other main subject discussed was the "Training of Archæologists". The point was strongly made that excavators must receive a sound training in field work. Archæologists in the past had mainly learnt from experience and experiment, usually at the expense in the early stage of a partial destruction of the evidence of an archæological site, and it must be realized, as Mr. I. A. Richmond said, that Roman villas do not exist to provide a Roman holiday for amateurs. The need for training in the environmental sciences was stressed by Dr. F. E. Zeuner. Archæologically-minded geologists and biologists should acquaint archæological students with the processes or phenomena investigated by those sciences, in order that they may know how best to make use of the specialists.

The results of the Conference may thus be summarized: the setting out of the vital contribution which archæology can make to the education of mankind, and the means by which this can be achieved; the emphasis laid on the need for additional financial resources, and the suggestions as to how these should be forthcoming from the State; and the suggestions as to how archæologists should be trained. The Conference closed with a resolution that the problems should be referred to the appropriate bodies for action, those affecting Britain to the newly formed Council for British Archæology, and those affecting work overseas to the societies interested, with the suggestion that they should set up an appropriate organization to deal with them.

OBITUARIES

Prof. Frank Schlesinger

THE name of Frank Schlesinger will always be associated with the determination of stellar parallaxes, for to him is mainly due the considerable knowledge of stellar distances that we now have. It was a fortunate circumstance that his postgraduate research was carried out at the Columbia University, where at the close of the nineteenth century astronomical research work was mainly concerned with the problems of the accurate determination of star positions by means of photography. The great possibilities that photography offered in this field were just beginning to be realized. Schlesinger's thesis for the Ph.D. degree was concerned with the accurate measurement and reduction of photographs of the Præsepe cluster, obtained by Rutherfurd, and showed originality of mind, a thorough grasp of fundamental principles, and ingenuity of method. He was quick to see the possibilities that photography offered for the accurate determination of stellar parallaxes. A short paper, published in 1899, entitled "Suggestions for the Determination of Stellar Parallax by means of Photography", referred to the neglect of this important subject and estimated that not more than twenty-five or thirty stars had known parallaxes which could be relied on to within 0·05″. It outlined methods which Schlesinger was himself afterwards to develop, and showed that he already clearly saw the main precautions that were needed to obtain accuracy.

A few years were to elapse, however, before Schlesinger could try out the suggested methods. He was appointed in 1899 to take charge of the newly established International Latitude Observatory at Ukiah, Ca., but the opportunity came with his appointment in 1903 to the staff of the Yerkes Observatory. He at once started parallax observations with the great 40-in. refractor. In a remarkably short time he developed methods that have since been closely followed by every observer who undertakes the determination of stellar parallaxes. In 1905 Schlesinger was appointed director of the Allegheny Observatory, which had just been reorganized, and for a time his attention was devoted to other problems, mainly of a spectroscopic nature. The results of the work at Yerkes were published in 1910–11 in seven important papers, which have deservedly become classics in this field of investigation. The methods of observation, the possible sources of error and how they could be eliminated or reduced to a minimum, the methods of measurement and of reduction were all comprehensively discussed. For the measurement of the plates Schlesinger designed an excellent long-screw measuring engine, which was made by Brashear. Many other engines of the same design have since been made by Gaertner.

It was characteristic of Schlesinger, when planning large programmes of observations, to consider carefully the accuracy attainable in relation to the expenditure of time in observation and measurement. There is generally a point beyond which further accuracy can be obtained only at the expense of a disproportionate increase in time and labour. As an example, Kapteyn had proposed that parallax plates after exposure should be stored undeveloped for six months or so and then exposed again, so that the parallactic displacement could be determined by differential measurements and the effects of film distortion eliminated. The method involved considerable wastage of material, because ideal conditions at the two epochs could never be obtained, and there were also many possibilities of plates being spoilt by accidents of one sort or another. Schlesinger thoroughly investigated film distortions and proved that their contribution to the final probable error was so small that the slight gain in accuracy was outweighed by the wastage of material and the other disadvantages of the method.

The observations in his short time at Yerkes enabled Schlesinger to determine twenty-eight parallaxes, with an average probable error of ± 0·013″. In 1914, on the completion of the Thaw 30-in. photographic refractor, he started parallax work at Allegheny. In six years he determined 365 parallaxes and obtained plates for several hundred additional ones: the probable error of these parallaxes was about ± 0·008″. He also arranged a carefully planned scheme of co-operation between the seven Observatories of Allegheny, Dearborn, Greenwich, Leander McCormick, Mount Wilson, Sproul and Yerkes. In 1924 he published a "General Catalogue of Stellar Parallaxes", containing the parallaxes of 1,870 stars, all but a few of which were the outcome of this scheme of work.

But this advance in knowledge was restricted to the northern portion of the sky, and Schlesinger therefore began to consider the possibility of erecting a large refractor in the southern hemisphere to remedy the deficiency. In 1920 he was appointed director of the Yale Observatory and was able to bring these plans to fruition. A 26-in. refractor of 36 ft. focal length was set up in the grounds of the University of the Witwatersrand, Johannesburg. The telescope and its housing were designed for the specific purpose of parallax determinations; as the observations are always obtained near the meridian, the motion of this telescope in right ascension is limited to about half an hour either side of the meridian, thus reducing considerably the cost of the installation. Co-operation with the Cape Observatory was also arranged, and the output of these two Observatories has been so considerable that the deficiency of knowledge of parallaxes of southern stars has been made good. The second edition of the "General Catalogue", published in 1935, contains trigonometrical parallaxes of about four thousand stars; including parallaxes determined by spectroscopic methods, the calibration of which is based on trigonometrical parallaxes, it gives the parallaxes of 7,534 stars. The "Catalogue" is not a mere compilation; it is based on a careful critical discussion of accidental and systematic errors to ensure that the probable errors assigned to the individual parallaxes are statistically correct.

Schlesinger's other main work was the determination of star positions from wide-field photographs. The basic ideas were to lighten the burden on the meridian observer, by restricting meridian observations to the brighter stars, and to determine the positions of fainter stars more accurately as well as more economically by photography. Plates covering a large field were necessary to ensure that each plate should contain sufficient of the brighter stars to serve as reference points. Plans for a programme with a lens covering 25 square degrees were drawn up in 1915 and the positions of stars in three zones, each extending over 5° in declination, were determined. Schlesinger then changed to a lens of 5·6 in. aperture and a focal length of about 80 in., using plates measuring 48 cm. by 58 cm., covering an area of 10° in declination and 14° in R.A., with a scale of approximately 100″ to 1 mm. Somewhat later he substituted a more efficient lens of 5-in. aperture, with plates 43 cm. square, covering 112 square degrees. The wide-angle lens camera was mounted on the large refractor at Johannesburg for photographing the southern stars. The measurement and reduction of these large plates introduces a number of delicate technical problems which Schlesinger solved with consummate skill. As the programme proceeded, various modifications and refinements were introduced for greater convenience and accuracy. His latest catalogue, recently published, has probable errors of a catalogue position of ± 0·105″ in each co-ordinate. Since 1925 the positions of some 77,000 stars have been published, a remarkable achievement for a single observatory with a small staff, and a tribute to the efficiency of Schlesinger's methods.

Schlesinger received the honorary degree of Sc.D. from the Universities of Pittsburg and Cambridge. He was elected an associate of the Royal Astronomical Society in 1914 and was awarded its Gold Medal in 1927. He was awarded the Valz Prize of the Paris Academy in 1926 and the Bruce Medal of the Astronomical Society of the Pacific in 1929. His election as president of the International Astronomical Union for the period 1932–35 was a fitting climax to a career of solid achievement. He retired in 1941 but, though he suffered much ill-health in his last years, he continued his work on the zone catalogues to the end. He died on July 10, at the age of seventy-two. He was a man of great understanding, wise in counsel, loyal in friendship and trusted by all.

H. SPENCER JONES.

Mr. C. V. B. Marquand

CECIL VICTOR BOLEY MARQUAND, only son of Ernest David Marquand, author of a "Flora of Guernsey", was born at Richmond, Surrey, on June 7, 1897. He was educated at Elizabeth College, Guernsey (1906–10), Lycée Henri IV, Paris (1910–11), Bedford School (1911–13), and Christ's College, Cambridge, where he took his B.A. in 1919, proceeding to M.A. in 1922. During the War of 1914–18 he served in the Machine Gun Corps, and held a commission in the Royal Tank Corps, from which he was invalided out.

On leaving Cambridge in 1919 Marquand was appointed research assistant in charge of investigations on Avena at the newly established Welsh Plant Breeding Station, Aberystwyth, and published a paper on "Varieties of Oats in Cultivation" in the second Cereal Bulletin of the Station. This was undoubtedly a very useful piece of work, and supplied keys for the identification of all the varieties that could be got together at that time. In 1923 Marquand was appointed assistant (a title since changed to botanist) in the Herbarium of the Royal Botanic Gardens, Kew, and at first continued work on the grasses, but was soon placed in charge of the Chinese section of the Herbarium, and wrote numerous papers on the flora of Eastern Asia, including revisions of the campanulaceous genus Cyananthus (1924), the Old World species of Buddleia (1930), and the gentians of China (1937). He was also interested in the genus Cotoneaster, many species of which are cultivated in Great Britain. He had charge of the Bryophyta (mosses and liverworts), a group which he had always found very attractive, but his other official work naturally left but little time for its study. He combined a passion for mountaineering with a great love of wild Nature, and was an enthusiastic field-botanist, many of his happiest days being spent in bryological holidays in the Alps, the Scottish Highlands, and North Wales. His ecological interests were reflected in a paper on the Bryophyta of Arctic-alpine associations in Wales (1922), and he continued to take a keen interest in genetics during his period at Kew, though he published nothing further on the subject.

Though Marquand was physically very vigorous, his constitution seems to have been permanently affected by his service during the War of 1914–18, and he retired from Kew in 1939 on account of ill-health. He then went to live in the island of Skye, where he was able to devote himself to field-work on the Lower Cryptogams. His tragic death last June on a boating expedition in search of a rare alga came as a great shock to his many friends. Generous, and incapable of a mean action, Marquand was a pleasant companion on a botanizing expedition, which his wide range of interests, not to mention his very decided views, helped to cheer and enliven.

T. A. SPRAGUE.

WE regret to announce the following deaths:

Dr. H. G. Baynes, an authority on Jung's system of analytical psychology and author of "The Mythology of the Soul", on September 6, aged sixty-one.

Capt. F. O. Creagh-Osborne, C.B., formerly director of the Compass Department of the Admiralty, on September 1, aged seventy-six.

Sir Francis Fremantle, O.B.E., M.P., an authority on public health, on August 26, aged seventy-one.

Dr. Aleš Hrdlička, head of the Division of Physical Anthropology in the U.S. National Museum from 1910 until 1942, on September 5, aged seventy-four.

Lady Lockyer, widow of the late Sir Norman Lockyer, founder of NATURE, on September 9, aged ninety-one.

Dr. W. H. Metzler, formerly professor of mathematics in Syracuse University, on April 19, aged seventy-nine.

Sir James Morton, a pioneer in the British textile industry, on August 22, aged seventy-six.

Dr. Cecil Price-Jones, the authority on the sizes of blood cells, on August 29.

Prof. L. Susan Stebbing, professor of philosophy in the University of London (Bedford College), on September 11, aged fifty-seven.

NEWS and VIEWS

Ophthalmological Research at Oxford

AN appeal for £250,000 has recently been launched by the University of Oxford to endow a Research Department in Ophthalmology. The only other university department of this character in Britain at the present time is the Tennant Research Institute at Glasgow, though the Royal Eye Hospital, in conjunction with the Royal College of Surgeons, has recently founded a research chair in ophthalmology. In 1940 Lord Nuffield gave £25,000 to enable the University of Oxford to build a small temporary laboratory for the new reader in ophthalmology and to appoint a research biochemist. This laboratory has been open for a year and work on nutritional and other problems has been started. In 1941 the total blind population of England and Wales was 70,000. Although four and a half million pounds was spent on their welfare during that year, the amount spent on prevention was comparatively small. Apart from blindness, it is perhaps not generally realized how widespread are defects of vision in the population. In 1937, nearly one sixth of the school children medically examined were found with "defective vision and squint". The children in London had a higher proportion of defects than those outside. Recent study of orthoptics justifies the hope of advancement in the relief of these defects in children and emphasizes the need for more work along these lines.

Advances in the science of nutrition have shown that a large amount of preventable blindness occurs in countries where the standard of life of the population is low. For example, deficiency in vitamin A leads to much blindness in children in Ceylon. Although such acute vitamin deficiencies do not occur in Europe, the effect of prolonged sub-optimal nutrition on the eyes must be investigated. Another problem to be examined is the question of illumination in factories and elsewhere. Defective illumination is responsible for many industrial accidents, as well as causing eye-strain among workers, resulting in diminished output. These examples show that what is needed at the present time is collaborative research between the ophthalmologist and research workers in experimental sciences. The department which the University of Oxford hopes to establish will provide facilities for such studies. Oxford is a peculiarly suitable home for such a department, as it already has an eye hospital which has a tradition of research, and collaboration between the medical and non-medical sciences is well established.

Research on Coal

THE colliery owners of Great Britain will provide a further sum, of the order of half a million pounds, for coal research, in order to extend their existing programme, which itself involves the expenditure of £1,000,000 over the current five years. It will be recalled that the Parliamentary and Scientific Committee recently urged a great expansion of utilization research into coal derivatives, adding that although the work should be generously subsidized by the Government, it should be carried out by industry itself. The new programme now announced by the Mining Association of Great Britain relates to the development of processes for producing hydrocarbons and hydrocarbon derivatives from coal, and to the treatment of coal generally as a chemical raw material. It will be put in operation immediately, and the colliery owners will themselves contribute £400,000–£500,000 towards its cost during the period ending with 1945.

Coke and Coal Research

THE investigations of Prof. H. L. Riley at King's College, Newcastle-upon-Tyne, and also those of Dr. R. A. Mott at the University of Sheffield, are concerned with problems affecting the hard coke industry, which enjoys facilities for large-scale experimentation through its member firms such as can only be available to industrial bodies of this kind. The research committee of the body organizing this work visited the Kingston and Fulham Laboratories of the British Coal Utilisation Research Association on September 9. Mr. J. G. Bennett, director of B.C.U.R.A., gave a short address, outlining the organization of his Association and the scope of the work it has in hand. Three main divisions can be distinguished, namely, the administrative, the general research division, and the specialized research departments, the latter subdivided into four or five sections. Within several of the specialized sections there are investigations in progress which will undoubtedly affect coke-oven practice and the quality of the coke that can be produced from a given coal or blend. In particular may be mentioned the 'heat-of-wetting' test developed in the Association's physico-chemical laboratory under Dr. D. H. Bangham. This, and other fundamental work on the structure of coal and coke, was discussed at the recent Conference on the Ultra-Fine Structure of Coals and Cokes held at the Royal Institution. The visitors spent most of their time at Kingston, where they inspected work on the production of high temperatures from solid fuel and other interesting aspects before proceeding to the main building recently opened by Sir Edward Appleton.

Otto Jespersen and an International Auxiliary Language

EARLY this year Prof. O. Jespersen died in Copenhagen. He was a philologist of world-wide reputation who specialized in the English language, was the author of various standard works, and a firm believer in the practicability of an international auxiliary language. His work in this connexion has been ably summarized by H. Jacob in a brochure published by the International Language (Ido) Society of Great Britain, in which we read of Jespersen's active part in elaborating Ido as a revised version of Esperanto, and of his subsequent invention, in 1928, of a new constructed language, called Novial. He was convinced that an international auxiliary language should be based on the material of European languages, should be regularly constructed, have a complete grammar of its own, be flexible and independent of national usages. He emphasized how incomparably easier it is to learn and use such a constructed language than any ethnic language, a view that has been confirmed as the result of a six-years' test by Prof. Thorndike in the United States. English he regarded as easier than other languages, but it would have to be drastically altered, in regard to spelling, grammar, etc., to make it sufficiently simple for international use. Nor has Jespersen any use for Pidgin English: "it would be laughed at and mocked at, and all those millions who know and love the old English language would not consider it a serious attempt to solve an important problem, but would turn away with horror". The attempt to make English an international auxiliary language by reducing the vocabulary is held by many to be invalidated by the many different meanings which some words possess; thus the "New English Dictionary" ascribes sixty-four distinct senses to 'give', sixty-three to 'take', and twenty-five adjectival senses to 'clear'. As the outcome of a life-long study of linguistics, Jespersen believed that language is moving towards ever greater simplicity and perfection; and he quoted Turgot's saying: "Des hommes grossiers ne font rien de simple. Il faut des hommes perfectionnés pour y arriver". This Ido publication can be recommended to all interested in the subject, and especially as it shows no unreasonable bias in favour of its own language.

Centenary of the *Economist*

THE centenary number of the *Economist* worthily maintains the tradition of impartial examination of public affairs which it has established from the days of James Wilson and Walter Bagehot. The factual approach, acute analysis, constructive criticism and the flair for asking the right questions which have characterized it from the start are faithfully reflected in the pages of the centenary issue. Few periodicals can have done more to stimulate the consideration of social and economic questions in the cool serious spirit of science, and it is fitting that in congratulating the *Economist* on the attainment of its centenary, men of science should put on record their appreciation of the contribution which that journal has rendered to the advance of science. In the centenary issue scientific workers will find the articles on "Enterprise and Efficiency", on the Middle East Supply Centre, entitled "An International Example", on nationalization and on "Active Citizenship" of particular interest, but scarcely less stimulating and suggestive is that on "Britain in the World" and the review of the first hundred years and of the policy of the *Economist* which open the issue.

Academy of Sciences of the U.S.S.R.

THE continuing activity of the Academy of Sciences of the U.S.S.R. is indicated in information recently received from Moscow. Two sessions of the Academy were held in Sverdlovsk last year, and another is being held in Moscow this month. All kinds of fundamental research are being maintained despite the urgent claims of war work. Although in the U.S.S.R. scientific workers are exempt from conscription, many volunteered for military service when war with Germany broke out. It is vigorously maintained that this is a "scientists' war", demanding the continuation of scientific research, and in the list of essentials for victory achievements in mathematics, physics and agriculture are given equally high priority with achievements in fields more immediately associated with war. At the forthcoming session, thirty-six new full members of the Academy and forty-two corresponding members will be elected. Among the candidates for election are Drs. Kharkov, Kirill, Sinelnikov and Leipunsky, who are known in Great Britain for their work at the Cavendish Laboratory, Cambridge, and also the polar explorers Vladimir Bize and Nikolai Yukov.

Earthquake in Japan

ACCORDING to radio reports from Tokyo, a serious earthquake took place in southern Japan during the afternoon of September 10. The area most affected appears to have been near Tottori, in which town half the buildings collapsed and more than 1,400 people may have been killed or injured. Tottori is some 100 miles north of Kobe where the earthquake was felt. The shock was also strong at Osaka. Around Tottori railway lines were blocked and telegraph communications were interrupted for a distance of 60 miles to the west. So far no news has been given concerning the area east of the town. Further news is awaited, though it is doubtful in the present state of conflict whether full details of damage done will be available.

The last great shock from near the epicentre appears to have been some sixteen years ago, when 3,000 persons were killed. Earthquakes in the Japanese Islands are relatively frequent, and such as those of July 15, 1941, in the Nagano Prefecture, when thirty houses collapsed killing five people and injuring twelve more, and May 2, 1939, in the Akita district, when 573 houses were completely shattered and 1,218 damaged, killing twenty-six people and injuring twenty-eight others, are common. Most people, however, remember the great earthquakes of Kwanto in 1923, which almost destroyed Tokyo and Yokohama, Tango in 1927 and Idu in 1930, which were fully described by the late Dr. C. Davison. The instability of Japan is part of the instability of the whole of the circum-Pacific circle, though in the case of Japan the instability appears to be enhanced by the proximity of high mountains and great ocean deeps.

'Natural' and 'Supernatural'

IN an article in the *Hibbert Journal* of April 1943, Mr. G. N. M. Tyrrell discusses the ideas which underlie the terms 'natural' and 'supernatural' and suggests that the emphasis so often laid on the words 'nature' and its derivatives is possibly due to a fear that what he calls 'supernature' may try to return. Pointing out that both in psychology and psychical research we find factors in personalities which have properties midway between those of conscious mind and unconscious matter, Mr. Tyrrell proceeds to say that it is now useless to try to defend an outmoded cosmogony in the face of scientific knowledge. The division between the natural and the supernatural must, he says, be discarded; what is wanted is a fuller appreciation of the fact that the question of objectivity and subjectivity is a question of how much or how little do we ourselves contribute to our own world. As Sir Arthur Eddington has put it, when referring to theoretical physics: "the mathematics is not there till we put it there".

Captain Thomas Sumner (1807–76)

JUST a century ago the first edition was published of Sumner's "New and Accurate Method of Finding a Ship's Position at Sea", which contained the first description of the "position line" now universally used both at sea and in the air when navigating by the heavenly bodies. An article by R. S. Richardson (*Pub. Astro. Soc. Pacific*, **55**, 136; 1943) contains some hitherto unknown biographical details of the man who so profoundly changed the methods of navigation. The facts have come to light as the result of a patient search by Dr. W. Van Lennep in the Harvard Library. Sumner was the son of a Boston architect and entered Harvard at the age of fifteen, three years ahead of Benjamin Peirce, later to become the professor of mathematics whom Sumner consulted regarding the merits of his method. At Harvard he studied mathematics and astronomy under John Farrar. Graduating in 1826 at the age of nineteen, he proceeded to sow his wild oats to such effect that in 1829 he found it advisable to enlist as a common sailor in the China trade. Within eight years he had risen to the rank of captain and was master of his own vessel. In 1837 he made the famous journey during which he discovered in dramatic fashion the principle of the position line. After six years presumably spent in testing the method and preparing the MS. of his book, he finally published the work in July 1843. It won instant recognition. It was supplied to every vessel in the U.S. Navy in the year of publication, and ran through several editions in the next decade. During this time, however, Sumner's mind was failing. In 1850 he was committed to a Boston lunatic asylum; in 1855 he was "hopelessly deranged"; and in 1865 he entered the Lunatic Hospital at Taunton, Mass., where he died of apoplexy at the age of sixty-nine, having spent in mental darkness the last twenty-six years of a life full of early promise. No doubt the tragic circumstances of his later life are sufficient explanation of the fact that the standard biographical dictionaries do not record so much as the dates of his birth and death.

Colonial Economic Advisory Committee

THE Secretary of State for the Colonies has set up a Colonial Economic Advisory Committee to give him advice on matters of general economic policy in the Colonial Empire. The members of the committee are: The Duke of Devonshire, Parliamentary Under-Secretary of State (chairman); Mr. G. I. M. Clauson (vice-chairman); Lord Hailey; Sir Bernard Bourdillon; Sir William Goodenough; Sir John Hay; Sir Hubert Henderson; Sir Harold Howitt; Mr. A. Dalgleish; Mr. E. F. M. Durbin; Mr. J. Hallsworth; Mr. J. McFadyen; Mr. J. McLean; Captain B. H. Peter; and Prof. L. C. Robbins. The terms of reference are: "To advise the Secretary of State on such questions of economic policy in relation to the Colonial Dependencies as he may refer to the committee, including particularly matters of general policy arising on programmes of economic development."

B.B.C. Broadcasts on Applied Physical Science

THE British Broadcasting Corporation is arranging a series of twelve weekly talks beginning on October 1 under the title "Science at your Service", on applied physical science. An attempt is to be made to bring before the layman the numerous ways in which physical science is being used in everyday life and to show that an understanding of the principles of science is essential in the post-war world. The addresses will deal with the home, building construction, plastics, clothing and fabrics, explosives, the structure of the earth's crust, the weather, planning fisheries, life-saving at sea, shipbuilding and tunnelling. It is expected that the speakers will include Sir Lawrence Bragg, Sir Edward Appleton, Sir George Burt and Sir Charles Darwin.

Industrial Health and Disease

A WEEK-END course for medical practitioners on factory medical services and industrial diseases will be held at the London School of Hygiene and Tropical Medicine during October 2–3. The course will be opened by Dr. E. R. A. Merewether, senior medical inspector of factories, and lectures will be given on the clinical approach to industrial medicine, occupational pneumoconioses, anæmia in war-time, nutrition and vitamins in war-time, prevention of industrial dermatitis, and rehabilitation with special reference to minor injuries. The fee for the course is one guinea, which should reach the secretary of the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.1, not later than September 27.

Inhibition of Urease by Penicillin

In treating patients with penicillin, our interest has been attracted to the problem of assay of the drug. Difficulties in this connexion are attached to clinical as well as laboratory studies, since it would be of considerable assistance in formulating principles for therapy to be able to measure small, sub-bacteriostatic quantities in the circulating blood. An attempt has therefore been made to discover easily measurable properties of penicillin, and we have found that even highly purified preparations will inhibit the activity of urease.

It has been necessary in this laboratory to work with macro-methods—a technical limitation that has compelled us to employ quantities of drug far in excess of the minimum producing bacteriostasis. Inasmuch as penicillin is extremely valuable and difficult to obtain, we have not attempted to study in detail the quantitative relationships involved.

Urease (Squibb) was prepared as 0·05 per cent solution in phosphate buffer, *p*H 7·3, and 1 ml. was used for each test. Penicillin in the uniform volume of 0·25 ml. water was added to the enzyme solution and the mixture allowed to stand for two hours at 37° C. Urea was made up as a 6 per cent solution in phosphate buffer, *p*H 6·4. 5 ml. of the same buffer was added to the final test solution to bring total volume to 6·75 ml. Urease activity was measured by the aeration method of Van Slyke and Cullen, as ammonia liberated in thirty minutes at room temperature from 30 mgm. urea.

Results of representative experiments are given in the accompanying table. For the most part, a commercial preparation (Merck) containing about 200 Oxford units per mgm. was employed. A large part of this material was composed of impurities which might well have accounted for some of the inhibition obtained. Indeed, attempts to demonstrate alteration in activity after forms of chemical and physical treatment known to destroy bacteriostatic agents produced effects that could not be clearly interpreted. A decrease in the degree of inhibition did occur after acidification, alkalinization and heating; but since the nature and variety of the impurities was unknown, this proves little with respect to the bacteriostatic agent. Of considerably more significance is the fact that a pronounced effect was obtained with samples of highly refined barium salt of penicillin*. This material contained 850 units per mgm. and was thus more than four times as pure as the Merck penicillin. In terms of amount of bacteriostatic agent, both preparations displayed about the same degree of inhibition of urease. On the other hand, the absolute weight employed was in one case 2 mgm. and in the other 7·5 mgm. This may be taken as evidence that the inhibitory activity is largely independent of impurities present.

Effect of Penicillin on activity of Urease.

5	0	0·78 ,, ,, ,, ,,
	1700 (Purified Ba salt)	0·34 ,, ,, ,, ,,

It would appear that final proof of the action of the bacteriostatic agent in this respect must await the ultimate stage of refinement of penicillin. Meanwhile although speculation with regard to the significance of these observations is perhaps premature, it may at least be pointed out that the peculiar elevation of blood-urea occurring in some patients under treatment with the drug[1] becomes of direct interest. For there is no clear analogy here to familiar clinical disorders that are characterized by urea retention. The absence of albuminuria and the prompt fall in the level of blood-urea upon withdrawal of penicillin argue against a disturbance of the excretory mechanism. An examination of the data given by the Floreys for their patients[1] reveals a relation between dosage of penicillin and the development of elevated blood-urea. Of five adults who received daily an average of 120,000 units or more, four showed a rise in blood-urea, whereas of four who received an average of 100,000 units or less, three maintained a normal level. The suggestion is made that this might be attributable in part to *in vivo* inhibition of urease.

Iron Excretion and Metabolism in Man

Until 1937 it was generally considered that iron was absorbed with some measure of freedom in the duodenum and upper parts of the small intestine, and that any taken up in excess of the immediate requirements of the body was excreted into the large intestine. In that year we pointed out that if one neglected the traces of iron always present in the urine and in abraded cells there was no convincing evidence that iron was ever excreted by any of the organs of the body, and that most of the work which had been done tended to show that iron once absorbed remained inside the body[1]. In the years which followed we brought forward experimental evidence to support this theory[2,3,4] which must now be considered also to be well supported by other people's data[5,6,7]. Within the last six months, however, we have had the opportunity of putting the theory to a searching test, and the results have been so convincing that we feel justified in placing them on record.

Mrs. H., aged sixty-six, fit, active and well until September 1942, was admitted to Addenbrooke's Hospital under the care of Dr. Leslie Cole in January 1943. She was found to be suffering from a very severe hæmolytic anæmia, and was specially investigated by Dr. Jacobson. She was kept alive only by frequent transfusions, and between February 11 and May 24 she was given twenty-eight pints of blood, all of which she hæmolysed. This blood must have contained about 8 gm. of iron, and its administration and hæmolysis in just over a hundred days means that about 80 mgm. of the metal were being set free inside the patient every day. If one considers that in the previous September, Mrs. H., as a normal woman, probably contained no more than 4 gm. of iron, it will be appreciated that she was being given more iron than she could possibly require, and that then, if ever, she should have been excreting it.

Between April 16 and May 18 we measured Mrs. H.'s intake and output of iron by the natural channels[8]. Over a period of seventeen days the iron in her food averaged 5·6 mgm. per day. Her urine contained 0·3 mgm. a day and her fæces 4·9 mgm., making a total excretion of 5·2 mgm. She was therefore in the slight positive balance of 0·4 mgm. a day, and there was no suggestion that Mrs. H. was excreting any of her superfluous iron. One can only suppose that she was unable to do so.

Much of the retained iron was undoubtedly stored in the liver, but all the organs probably participated to some extent. We have only had the opportunity of analysing her spleen, for Mrs. H. was cured by its removal on May 25. The organ was enlarged and weighed 350 gm. It contained 0·32 gm. of iron, only a fraction of the amount which had been given.

If the body never excretes iron, it follows naturally[1] that the amount absorbed must fluctuate in accordance with the requirements of the body. Using radioactive iron, Hahn *et al.*[9] showed that this was true for normal and anæmic dogs, but there is still a great deal to be found out about the absorption of iron, and about the ways in which this absorption is adjusted and controlled.

l-Lysine Decarboxylase: Preparation of Specific Enzyme and Coenzyme

Strains of certain bacteria produce specific amino-acid decarboxylases when grown under acid conditions[1]. A cell-free preparation of *l*(+)-lysine decarboxylase has been made from acetone-dried powders of selected strains of coliform organisms grown for 24 hr. at 25° in 2 per cent glucose casein-digest-broth. A suitable paracolon organism, *Bact. cadaveris*, has been deposited in the National Collection of Type Cultures*. The powder is extracted for 2 hr. at 37° with *X* ml. *M*/45 borate buffer *p*H 8·5 (1 ml. per 20 mgm. powder) and the sediment then centrifuged off. Ethanol is added to the supernatant to a concentration of 20 per cent, the *p*H adjusted to 5 with acetic acid and *X*/2 ml. alumina Cγ suspension (16 mgm./ml.) added immediately. The alumina is twice eluted with *X*/2 ml. *M*/5 phosphate *p*H 7·0 and the enzyme precipitated from the combined eluates by the addition of 50 gm. solid ammonium sulphate per 100 ml. The precipitate is dissolved in water and insoluble material centrifuged off. The opalescent supernatant fluid can be used as a source of specific enzyme or purified a further 10–12 times by fractional ammonium sulphate precipitation as shown in the accompanying table.

Steps in the purification of *l*-lysine decarboxylase from a strain of *E. coli*.

Stage	Preparation	Ml.	Mgm. C/ml.	Total units	$Q^{C}_{CO_2}$

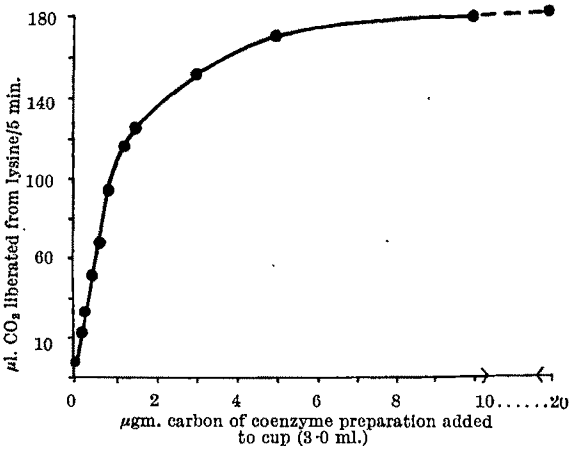
	(c) 47–52% ,, ,,	10	0·49	131	32,000

The enzyme is tested manometrically at 30° in the presence of 2 ml. *M*/5 phosphate buffer *p*H 6·0 and 0·5 ml. *M*/15 *l*(+)-lysine, the carbon dioxide evolution followed over the first 10 min. after mixing and activities expressed as $Q^{C}_{CO_2}$ = µl. carbon dioxide liberated/hr./mgm. carbon of enzyme preparation. Carbon contents are estimated by the method of van Slyke and Folch[2]. One unit of enzyme is defined as that amount liberating 100 µl. carbon dioxide from lysine in 5 min. Under these conditions, the preparation at stage 5 can be used for the rapid estimation of *l*(+)-lysine; using 0·5 ml. of such a preparation in each manometer for the estimation of 0·5 ml. *M*/30 lysine (theory = 373 µl. carbon dioxide) a series of nineteen tests gave mean gas output of 344 µl.; stan. dev. 4·7; range 337–354. This output represents 92 per cent theory, but if carbon dioxide retention is estimated by the 'acid-tip' method[3], then the output represents 98 per cent theory.

The enzyme is optically specific and has been used for the resolution of *dl*-lysine and the preparation of *d*-lysine. Of the sixteen amino-acids previously listed[1], *l*-lysine is the only one attacked. The molecule is not attacked if it is acetylated in the α or ε position. Samples of hydroxylysine kindly given by Dr. D. D. van Slyke were slowly, but incompletely, attacked. The enzyme is optimally active at *p*H 6·0 and has a Michaelis constant of 0·0028 *M*. The preparations are rapidly and irreversibly inactivated by dialysis against water.



EFFECT OF COENZYME CONCENTRATION ON RATE OF DECARBOXYLATION OF *l*-LYSINE BY SPECIFIC PROTEIN

Manometer cups contain: 0·25 ml. specific protein solution; 0·5 ml. *M*/15 *l*-lysine; 2·0 ml. *M*/5 phosphate buffer *p*H 6·0; 0·25 ml. coenzyme solution containing amounts above.

Two or three successive precipitations of the protein (stage 5) with 60 per cent saturated ammonium sulphate containing 10 per cent ammonia result in the preparation of an inactive protein reactivated by the presence of boiled enzyme, boiled yeast or bacteria, etc. The specific protein cannot be reactivated by coenzymes I or II, flavineadeninedinucleotide, flavinephosphate, thiamin, thiamindiphosphate, etc., alone or in combination. Spectroscopic examination of ashed enzyme does not reveal the presence of any metals. The addition of extracts of boiled tissues to the specific protein shows that the coenzyme has a wide distribution, being present in rat liver, skeletal muscle, heart, kidney, brain and gut; brewer's and baker's yeast; all bacteria tested, and in cabbage leaves and the garden pea. It is not feasible at present to work up bacteria, so brewer's yeast has been chosen as the richest convenient bulk source for the isolation of the coenzyme.

The coenzyme can be extracted from air-dried brewer's yeast by weak alkali but not by water or acid. Since the barium salt is soluble in water, the yeast is first extracted with ten times its weight of 0·75 per cent baryta solution in the cold. Barium is removed from the extract with sulphuric acid and the neutralized centrifugate poured into 5 vol. alcohol. After removal of the precipitate, barium acetate is added to the filtrate and the precipitate collected. The coenzyme is apparently adsorbed on the barium sulphate under these conditions and can be purified some thirty times by exhaustive washing of the precipitate with hot water, followed by decomposition in sulphuric acid. The acid centrifugate is extracted with phenol to remove flavine-like substances, saturated with ammonium sulphate and re-extracted with phenol. The coenzyme is removed from the second phenol extract by shaking with water in the presence of ether. The water solution is acidified with nitric acid, extracted with *iso*-butyl alcohol, the coenzyme extracted from the alcohol with *N*/10 sodium hydroxide and precipitated as the lead salt. The final stage consists of alcohol fractionation of the barium salt. The purest fraction so far obtained is precipitated by 30 per cent ethanol, but a further, slightly less pure, fraction can be obtained by increasing the ethanol concentration to 50 per cent, dissolving the resulting precipitate in water and refractionating with 30 per cent ethanol. The coenzyme can be dried and kept indefinitely as the lead salt. From 1 kilo. dried yeast a yield of 15–20 mgm. lead salt (0–30 per cent ethanol fraction) can be prepared.

This preparation, after removal of the lead as lead sulphate, will activate the specific protein as shown in the accompanying figure, the half-saturation value corresponding to a concentration of 0·27 μgm. C of coenzyme preparation per ml. Over the range where the carbon dioxide liberation is proportional to the amount of coenzyme added, the activity, μl. carbon dioxide liberated/hr./mgm. carbon of coenzyme preparation, is 1,800,000. The coenzyme solution is deep yellow in colour, shows no flavine-like fluorescence, gives a positive Bial's reaction, and gives on analysis of the lead salt (Weiler): C, 22·18 per cent; H, 3·32 per cent; N, 5·07 per cent; P, 3·02 per cent; Pb, 41·2 per cent.

Tested enzymatically, the coenzyme is unaffected by boiling for 4 hr. in *N*/10 sodium hydroxide, but is destroyed in 60–90 min. by *N*/10 sulphuric acid at 100°. These hydrolyses are unaffected by reduction with cysteine or hydrosulphite. Work is proceeding on the nature of the groups in the coenzyme molecule, and it is hoped to publish full details in due course.

We are indebted to the Medical Research Council for a full-time grant to one of us (H.M.R.E.) and for a part-time grant for technical assistance.

Ultra-Violet Light and Apparent Vitamin C

I AM indebted to Dr. Griffiths[1] for pointing out the incorrect reference to the method of preparing reductone which inadvertently was included in our note published in NATURE of July 3. His suggestion that reductones might be produced by the action of the ultra-violet light in sunlight is of some interest.

We have carried out experiments on the irradiation of different dehydrated foods in air, using a mercury vapour lamp with filters to cut out rays below about 280 mμ which would not occur normally in sunlight, and have not obtained any evidence of formation of reductone. Our experiments were carried out on foodstuffs irradiated for different periods up to six hours in aqueous solution at 12 in. from the lamp, using air-filled glass containers (covered Petri dishes). The *p*H of the solutions was between 4 and 6.

Dye titrations on samples taken at intervals showed no increase in the content of reductones or other constituents of apparent vitamin C in foodstuffs in which considerable amounts of this could be produced by prolonged storage in the dark under normal conditions. When foodstuffs were used in which the apparent vitamin C had developed during storage in the dark, this apparent vitamin C was almost entirely destroyed by a few hours irradiation. This is in keeping with the finding of Euler and Martius[2] that reductone has an absorption maximum at 287 mμ at *p*H 5·7 or higher, shifting to 268 mμ at *p*H 4·0 or lower. It would therefore seem desirable in storage experiments on vitamin C to use containers of amber glass which does not transmit any radiation below 370 or 380 mμ. This should avoid photochemical destruction of apparent vitamin C in the form of reductone, reductic acid or dihydroxymaleic acid, also of true vitamin C, which Mohler and Lohr[3] found to have a subsidiary maximum at about 350 mμ in potassium cyanide solution, equivalent to about 340 mμ in water. There is evidence that the vitamin C in fruit syrup stored in white glass bottles under normal conditions may be destroyed by sunlight.

While our results have not provided any evidence for the production of apparent vitamin C by the action of sunlight on processed foods, the position may be different in regard to natural foods such as fruits which are subjected to prolonged solar radiation during ripening and contain enzymes and pigments which may modify the conditions.

FRANK WOKES.

Vitamin C and Carbohydrate Metabolism

IT has been shown previously[1,2] that deficiency of vitamin C in guinea pigs leads to a change in the carbohydrate metabolism as judged by (1) the glycosuria, (2) the diabetic type of the glucose tolerance curve, and (3) the depletion of the glycogen content of the liver. It has also been shown that the normal metabolism of carbohydrate is restored after the administration of vitamin C. From the above evidence, it has been suggested that the action of vitamin C is similar to that of insulin.

In the present investigation the insulin content of the pancreas of normal and scorbutic guinea pigs has been studied. Normal healthy male guinea pigs (200–300 gm. wt.) were selected. Some of the animals were fed on a scorbutic diet consisting of crushed barley, 64 parts; crushed gram, 20 parts; casein, 12 parts; common salt, 1 part; calcium carbonate 3 parts; cod liver oil, 2 c.c.; for a period of 24–28 days, until the animals developed scurvy. Other animals were fed on an ordinary diet consisting of green grass, germinated gram, outer green leaves of cabbage, etc., for two weeks.

Prior to the removal of the pancreas the animals were fasted overnight. The pancreases of 5–7 animals were pooled and extracted for insulin according to the method of Best *et al.*[3]. The crude insulin precipitate obtained was dissolved in normal saline of *p*H 2·5 so that 0·5 c.c. of the solution represented 1 gm. of pancreas. The potency of the solution was tested by studying the hypoglycæmic reaction in rabbits as described by Marks[4]. The results are shown in Tables 1 and 2. They definitely indicate that the insulin content of the pancreas is markedly diminished in scurvy.

TABLE 1. NORMAL GUINEA PIGS.

Aliquot No.	Number of guinea pigs	Weight of pancreatic tissue	Percentage blood-sugar reduction by the extract from 1 gm. of pancreas	Insulin content per gm. of pancreas
1	6	6·0 gm.	16·0	>1 unit
2	7	7·0	30·5	1·2 ,,
3	6	6·0	15·6	>1 ,,
4	7	5·6	13·0	>1 ,,

TABLE 2. SCORBUTIC GUINEA PIGS.

Aliquot No.	Number of guinea pigs	Days on scorbutic diet	Weight of pancreatic tissue	Percentage blood-sugar reduction with extract from 1 gm. of pancreas
1	5	26	5·5 gm.	0
2	6	24	6·0	0
3	5	24	5·0	0
4	6	28	6·0	0

International standard insulin was obtained through the courtesy of Dr. B. Mukerji, director of the Standardization Laboratory, Government of India. Thanks are due to Dr. B. M. Das Gupta, director of the School of Tropical Medicine, for his interest in the present investigation.

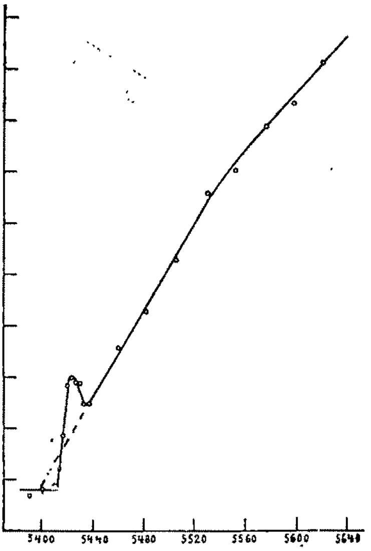
Short Wave-length Limit of the Continuous X-Ray Spectrum and Determinations of h/e

As is known, there exists a discrepancy between earlier determinations of h/e obtained from the short wave-length limit of the continuous X-ray spectrum and the value of h/e calculated from Bohr's formula for the Rydberg constant. Thus most of the determinations of h/e by the X-ray method have given values that are 0·3–0·4 per cent lower than the value calculated. This difference is several times greater than the stated limits of error, indicating the presence of systematic errors in the measurements. An error of this nature, due to too high a pressure in the X-ray tube, has previously been pointed out by me[1]. This error can amount to 0·1–0·15 per cent and is therefore too small to account for the whole of the discrepancy. Further, a number of determinations of h/e have been carried out by means of technical X-ray tubes in which the pressure was sufficiently low.

In the determinations of h/e carried out by me[2], with the aid of a bent crystal and Geiger counter, a very narrow spectral band could be used on account of the greater intensity of the method, and the voltage was varied by very small steps (about 2 volts). Only the very lowest part of the isochromats, up to about 10 volts from the threshold voltage, was investigated. This part of the curves proved to be linear and gave a sharply defined determination of the threshold voltage. The value obtained, $h/e = (1{\cdot}3787 \pm 0{\cdot}0008) \times 10^{17}$ erg. sec./E.S.U. agrees within the limits of error with the calculated value. In a later paper[3] I have described how I investigated the isochromats by the same method, up to 40 volts from the threshold voltage. The curves proved to be linear up to 10 volts from the threshold, where a maximum was obtained. From 10 volts upwards the intensity sank, reaching a minimum at 20 volts and rising again thereafter, though less steeply than before. This indicates the occurrence of a systematic error, by extrapolating from the upper part of the curve.

I have now adopted a series of isochromats of the wave-lengths 2498·42 X.U. (vanadium $K\alpha_1$) and



2285·03 X.U. (chromium $K\alpha_1$) to investigate the size of this error of extrapolation. The illustration shows a curve taken at λ = 2285·03 X.U. Up to 20 volts from the threshold the voltage was varied in 2-volt steps and then in greater steps. The lowest straight part of the curve gives a value of the threshold voltage which agrees with the results of my previous investigations. On the other hand, an extrapolation from the upper part gives a value which is about 0·4 per cent lower.

In previous determinations of h/e broader spectral bands were used. The voltage was varied by steps that were too great to permit observation of the structure at the lowest part of the curves. The extrapolation therefore caused a systematic error and the values obtained were thus too low.

A precise determination of h/e by the isochromatic method is only possible, therefore, if a sufficiently narrow and well-defined spectral band is used, and the voltage varied by such small steps that the structure mentioned above appears.

A more detailed discussion of these problems will shortly be published in *Arkiv f. Matematik, Astronomi o. Fysik*.

Variations of Ultra-Violet and Daylight Rays

A DAILY record of daylight and near ultra-violet rays has been kept for the last eleven years, covering a sunspot cycle, at a site on the slopes of the Pennine hills about ten miles north-east of Manchester. The results of daily and seasonal observations are of considerable interest, but passing over these, attention may be given to what has taken place in the current solar cycle. At the time of sunspot minimum the daylight and ultra-violet rays had a maximum intensity; and as the number of sunspots increased, the light rays of both classes gradually diminished, and at the sunspot maximum, which occurred in 1937, they came sharply to a minimum intensity. Since then, as the sunspots have grown fewer in number, the rays have again risen to greater intensity and are increasing in intensity as the period of sunspot minimum approaches.

The two classes of rays do not rise and fall at the same proportionate rate, the ultra-violet moving to the highest and falling to the lowest point more slowly than the daylight rays. A graph of the ratio of the ultra-violet to the daylight intensities brings this out clearly, and the graph, so far from being a straight line, shows that the ratio has a variation which agrees remarkably well with the variation of sunspots in the solar cycle.

Sir Edward Appleton[1] has shown that the ionization of the upper air changes in sympathy with the number of sunspots, and consequently the curve of ionization and the curve of the ratio of ultra-violet to daylight rays are closely alike. A consideration of these observations and relationships leads to a tentative view consonant with the facts.

Since ultra-violet and daylight rays are diminished and become least as the sunspot maximum is reached, when the sun is reputed to be most active, it would appear that the rays at that time must be impeded or absorbed. It is at that time that the ionization of the upper air is greatest, and if ionization is indicative of some condition which has the property, or is itself capable, of interfering with the passage of light from the sun to the earth, then the reduction of light intensity at this maximum period would be accounted for. When the impediment to the passage of light is lessened or removed, at the time of fewest spots and least ionization, increase of light intensity would be explained.

It might be expected that the increased activity of the sun at sunspot maximum would give rise to increased ultra-violet radiation, but according to Dr. Pettit of Mount Wilson Observatory[2], radiation of light from the sun could not vary, as it does, by 160–180 per cent in the solar cycle without a simultaneous large variation of the temperature of the sun, of the order of 1,000° C., and evidence for this is wanting.

It would seem that the large range of variation of ionization, and properties accompanying it, is set up by the emanation from the sun which is responsible for auroras and geomagnetic phenomena, and the large changes of ultra-violet and daylight rays are due to effects which accompany ionization and which behave as a partial shield to the rays.

The course of the *daily* and *yearly* variation of both classes of rays, which, however, are due to the changing altitude of the sun, also suggests that they suffer a partial shielding in a similar way.

It is probable that light radiation as it leaves the sun does not vary more than the variation of the 'solar constant', and the inequality of light received on the earth in the solar cycle is the result of an inequality of shielding.

It is interesting to watch at the present time, as the minimum of sunspots is approaching, the remarkable growth of light intensity. In 1937 at the maximum of sunspots, ultra-violet and daylight intensities were, in arbitrary units, 422 and 764 respectively, while last year they rose to 720 and 1,817 and are still rising.

Spore-forming Bacteria in Potatoes

IT is generally accepted by plant pathologists that no spore-forming bacterium (Bacillus) is directly responsible for disease in plants and that such as are associated with lesions are saprophytes or secondary invaders. Accounts and even detailed experiments[1] have appeared from time to time attributing pathogenic powers to certain species of the *subtilis* group, notably *Bs. mesentericus*, but these have not been confirmed.

In the spring of this year several lots of stored potato tubers affected by bacterial rot were submitted by the Ministry of Agriculture and Fisheries to me for investigation, and from one of these in which the interior had been converted into a gummy transparent mass a spore-forming bacterium was isolated. Provisionally identified as *Bs. polymyxa* (Prazmowski) Migula by Dr. T. Gibson of Edinburgh, this organism produces a complete rot with evolution of much gas when inoculated on to slices of fresh potato, carrots, onions, cucumber and iris stems. *Bs. polymyxa* was re-isolated from some of these slices and re-inoculated into a further series of slices with similar results. This has been repeated several times at temperatures varying from room temperature to 37° C., and there can be no doubt that the spore-former *Bs. polymyxa*, a normal inhabitant of soil, is pathogenic to plants under certain conditions.

Up to the present most bacterial potato rots have been ascribed to the well-known non-spore-formers, *Bact. carotovorum*, *Bact. aroideæ* and *Corynebacterium sepedonicum*, but from the present investigation it seems evident that under certain conditions of storage potato tubers can be rotted by some species of spore-forming bacteria. The conditions under which these bacteria are able to invade tubers are only partially known and merit more extensive investigation than has hitherto been accorded them in view of the serious losses caused. Further work is proceeding.

Colour of Red Blood Corpuscles

A SINGLE red blood corpuscle, illuminated by white light, appears yellow under the microscope. Why does it not appear pink ? I have asked distinguished zoologists, physiologists, histologists and authorities on colour-vision, but only one has given even a tentative answer, though all have agreed to the fact. The yellow appearance is mentioned by the authors of a few histological text-books, but they either make no comment or else suggest that one would expect yellowness on account of the thinness of the coloured layer. The change of colour of certain dyes on dilution is sometimes attributed to different degrees of dissociation of the dye molecule, but the yellow appearance of a single red blood corpuscle must clearly be attributed to some special phenomenon of colour-vision that is not a matter of general knowledge among biologists.

The subject is important apart from its intrinsic interest, especially in connexion with the application of chemical colour-tests to microscopical objects. It frequently happens that when a red or purple reaction is expected, a yellow appearance is given. This happens particularly with the various aldehyde reactions for tryptophane. Test-tube experiments show a purple or purplish-red reaction, and massive protein-bodies in cells show a similar colour. The cytoplasm itself, however, generally appears yellow in thin sections, and the interpretation is difficult. An understanding of the tendency of pale red objects to appear yellow would help in the interpretation of histochemical colour-tests applied to very minute objects, such as mitochondria and the dictyosomes of the Golgi element.

Length of Life of Sperms in the Woodlouse *Armadillidium vulgare* Latr.

RESULTS which could only be explained by the suggestion that sperms can be stored in females of *A. vulgare* for at least a year and that sperms are still viable after this storage have already been published[1,2]. Further evidence for this suggestion has now been obtained. In 1941 the two black females, *EC* and *EK*, were mated with the red males, *JDA* and *JDB*, respectively. Both females produced a brood in the summer of 1941 and they were both kept separate from males in the winter of 1941–42. Nevertheless both females again produced broods in the summer of 1942, and the composition of these broods (brood 176 from female *EC*, 20 red : 17 black; and brood 175 from female *EK*, 8 red : 4 black) shows that they were not produced by parthenogenesis since red colour is due to a single dominant gene.

Ocular Muscles and Vision

THE double function of the ocular muscles, as described in my letter in NATURE of April 10, p. 422, explains many illusions, one of which has been freely discussed without any satisfactory explanation. This refers to the apparent appearance of a moving motor-car or carriage, as if it were standing still. The eye on moving takes a fresh photograph, which is seen for an appreciable time. The decomposed visual purple is swept out of the way by the back pressure. Note the difference in appearance of a tennis or cricket ball when the eyes are still and when they are moving following the ball. A very curious example may be seen at a cinema. If, when an orator is speaking, the eyes be directed to another part of the picture and then immediately be turned back again to the orator, he will be seen quite still, with his mouth open or closed, while his voice goes on.

RESEARCH ITEMS

Blood Groups of the Tharus

The Tharus are a primitive people living mainly in fen-land areas of the United Provinces, Bihar and Orissa. Their total population as recorded in the 1931 census is 77,021. Women play a dominant part in Tharu society and the menfolk have adapted themselves to a subservient position. The traditional explanation of this is that the Tharus are offsprings of mixed marriages between Rajput women and their servants. D. N. Majumdar has taken blood samples from 241 males and 82 females, and his results show a very high incidence of the *AB* group (18·4 per cent for males, and 18·3 per cent for females) ("The Tharus and their Blood Groups". By D. N. Majumdar. *J. Roy. Asiatic Soc., Bengal* (Science), **8**, No. 1; 1942). The Tharus, living as they do in a malarious and unhealthy country, have been popularly known as immune from malarial infection. While measuring his sample, the investigator found a number of them suffering from fever, and he noted that most of the latter belonged to group *A*, whereas 78 per cent of the (*B*+*AB*) group said on inquiry they were not habitual victims of malarial infection.

Peruvian Skeletal Remains

The classification and racial relationships of much Peruvian cranial material are difficult to determine owing to artificial deformities. T. D. Stewart has studied metrically miscellaneous undated skulls from the Chicama-Moche-Virú region, and some smaller series from Cupisnique and Mochica graves ("Skeletal Remains from Cultural Associations from the Chicama, Moche, and Virú Valleys, Peru". By T. D. Stewart. *Proc. U.S. Nat. Mus.*, **93**, No. 3160). He comes to the conclusion that the undeformed Chicama series is about as homogeneous as the American undeformed crania available for comparison from one culture or site. He concludes, also, that there are certain significant differences between the deformed and undeformed series that are independent of deformity. There is a possibility that these differences likewise may distinguish the Cupisnique and Mochica remains, the only demonstrable morphological difference of which is based upon the presence of fronto-occipital deformity in the former case. His final suggestion, that the classification of Indian physical types should wait upon a better definition of skeletal material, will find support among other authorities.

Microbiological Degradation of Sterols

In general, the sterol content of soils has received little attention although the wide distribution of free or esterified sterols in animal and vegetable tissues must result, during their decay, in the deposition in soils of an appreciable quantity of sterol substances. G. E. Turfitt (*Biochem. J.*, **37**, 115; 1943) has determined sterol contents of certain British soils and finds that there are definite relationships between sterol content and soil type. Deposition of sterols must depend primarily on the nature and number of the animal and plant inhabitants, so that deposition will be at a maximum in soils favourable to the maintenance of a flourishing population. Extreme acidity, lack of aeration and excessive water content are all factors which, either individually or collectively, inhibit the decomposition of humus and its constituent sterols and are thus responsible for the high sterol content of bog and fen peats. These adverse factors have been counteracted in arable soils, and the content of any soil shows a gradual decrease when replenished by organic manuring. The disappearance of sterols from soils cannot be due to the leaching action of rain-water, since sterols are so insoluble in water, but is probably the result of decomposition by certain acid-tolerant aerobic bacteria.

Salmon of the Irish Rivers

The Fisheries Branch of the Department of Agriculture, Dublin, continues its series of researches on the Salmonidæ in Irish waters ("Salmon of the River Corrib, together with Notes on the Growth of the Brown Trout in the Corrib System", by Arthur E. J. Went. *Proc. Roy. Irish Acad.*, **48**, B, No. 12; 1943. "Salmon and Sea Trout of the Waterville (Currane) River", by Arthur E. J. Went and T. Sankey Barker. *Sci. Proc. Roy. Dublin Soc.*, **23** (N.S.), No. 9; 1943). A large amount of information has now been gathered together on this subject, not only on scales and other data but also on the nature of the waters and geological formations over which they flow. The tributaries of the River Corrib exhibit many diverse characters, ranging from quite acid to alkaline waters having *p*H values of 8·1. The Waterville (Currare) River contains little or no lime; the waters of this system being either neutral or acid. It has not yet been proved by actual examination of the migrating smolts whether those of the individual tributaries are distinctive, but it is suggested that the abnormally large smolts may have been derived from one special locality within the river system. The River Corrib with its varied conditions is ideal for carrying out such an investigation when post-war conditions will allow it, and it is suggested that it would be very interesting to ascertain whether the varied growth-rates of the brown trout in this system have a parallel in growth (and age at migration) of the young salmon from each of these localities.

Thrips Resistance in Cacao

The cacao thrips (*Selenothrips rubrocinctus* Giard) is native to tropical America but is now widely distributed and occurs in most cacao-growing countries. It ranks as an important pest in the West Indies, Brazil, and West Africa. It spends its life on the leaves and pods of the cacao tree, and when attacks are severe defoliation results. The resistance of particular plants to thrips attack is a subject that has been investigated by the Entomology Department of the Imperial College of Tropical Agriculture in Trinidad. A preliminary account of this inquiry by Dr. E. McC. Callan is contained in *Tropical Agriculture*, **20**, 127 (1943). The studies were initiated in 1939 and were based on the fact that it had been observed on occasion that certain individual cacao trees supported very few thrips when the surrounding trees were heavily attacked. Some thirty apparently resistant trees were selected, and of these twenty-seven were found in Trinidad and three in Grenada. Among them *RT*18 is the outstanding selection made, being not only thrips-resistant but also a good commercial type of cacao. Statistical analysis of thrips-population counts on this tree and four surrounding trees shows that the differences between the counts are highly significant, suggesting that *RT*18 is thrips-resistant. Population counts over a period of two years showed that the standard type of tree supports a population more than 7·5 times greater than that of *RT*18. The resistance property of cacao to thrips appears to reside in the leaf, which is to a large extent resistant to puncturing by the mouth-parts of the insect. A method is given of expressing the thrips resistance of a cacao type as a coefficient of resistance. The mean coefficient of resistance of *RT*18, namely, 0·87, is based on the assumption that the susceptible standard type of tree *ICS* has a coefficient 0 and an immune type a coefficient 1.

Cocksfoot Grass

Dactylis glomerata normally has $2n = 28$ chromosomes. *D. Aschersoniana* has $2n = 14$ chromosomes. A. Müntzing (*Hereditas*, 29, 134; 1943) has discovered two haploid plants $2n = 14$ among twin seedlings of *D. glomerata*. In regard to the morphology of the spikelets these haploids were similar to *D. Aschersoniana*, but differed in several other respects from this species. One plant was sterile and rather weak, whereas the other, although male sterile, set seed from pollination of *D. Aschersoniana*. In place of $2n = 14$, the ten seedlings obtained had $2n = 21$, $2n = 24$, and $2n = 28$. The relationship of *D. glomerata* and *D. Aschersoniana* is being studied by the author and it is significant that the haploids obtained from *D. glomerata* differ between themselves in several characters: probably as the result of differing genes on the four sets of chromosomes of the plant.

Oxidation of Nitric Oxide

INVESTIGATIONS of Bodenstein and co-workers showed that the reaction $2NO + O_2 = 2NO_2$ is termolecular and homogeneous; later workers claim to have obtained evidence that there are surface effects and that the reaction is not entirely homogeneous. Stoddart (*J. Chem. Soc.*, 5; 1939) reported curious results, which indicated that reaction did not occur when the oxygen was added to the nitric oxide, and drying was not necessary to inhibit the reaction. J. H. Smith (*J. Amer. Chem. Soc.*, 65, 74; 1943) has re-investigated the reaction, the concentration of nitrogen dioxide being determined by a colorimetric method. Data were obtained over a 100-fold variation of nitric oxide concentration, at pressures from 0·5 to 50 mm. and at the two temperatures 0° and 25°. At moderately high pressures, and at low pressures when adsorption effects are eliminated, satisfactory agreement with previous results was found. At very low pressures adsorption and surface effects became marked, indicating complications due to adsorbed nitric oxide, and oxygen to a less extent. The reaction may be regarded as essentially homogeneous, the irregularities being marked only at very low pressures. Stoddart's result was not confirmed and was perhaps due to the circumstance that only a slight amount of nitric oxide entered the oxygen bulb. The results of the effect of water vapour seem of little interest, since the apparatus was merely warmed in out-gassing, the nitrogen dioxide was in contact with tap grease, and it is not stated if purified phosphorus pentoxide was used.

The System Alumina-Water

Two forms of alumina Al_2O_3, namely, corundum and γ-alumina, two forms of aluminium oxyhydroxide AlO(OH), namely, diaspore and böhmite, and two forms of aluminium hydroxide $Al(OH)_3$, namely, gibbsite and bayerite, are well established. The so-called β-, δ-, ζ-, and trigonal aluminas are spurious. The transition points as found by dehydration methods vary as much as 200°. A. W. Laubengayer and R. S. Weisz (*J. Amer. Chem. Soc.*, 65, 247; 1943) have used the hydrothermal method, which consists in keeping the substance in contact with superheated steam in a bomb. The crystalline substances obtained were identified by chemical analysis and by X-ray and microscopical examination. The products formed at higher temperature (300°–500°) were well crystallized and could be identified by their optical properties. The main results are as follows. Corundum is the stable phase above 450° ± 5°; γ-alumina is metastable throughout the range investigated. Diaspore is stable below 450° ± 5° and its lower limit of stability seems to be about 280°; it was prepared artificially (probably for the first time, as previous claims are very questionable) by seeding γ-Al_2O_3, held at 430° (240 atm.) for 40 hours in water, with diaspore. Böhmite is apparently stable between 155° and 280°; gibbsite is unstable above 155°; bayerite is unstable above 155° and is probably less stable than gibbsite below this temperature. It is noteworthy that diaspore can be obtained only by seeding, and without seeding böhmite is formed in preference to diaspore, even though the latter should be stable in given conditions.

Theory of Cepheid Variables and Novæ

F. Hoyle and R. A. Lyttleton have developed a new theory of Cepheid variables and novæ which has many attractive features, though it must be admitted that it is highly speculative and presents certain complicated features (*Mon. Not. Roy. Astro. Soc.*, 103, 1; 1943). The authors postulate a binary system in which most of the mass of each component is confined to a relatively small volume, and a common atmosphere surrounds both components, but the material of the atmosphere does not take part in the orbital motion of the system. A periodic gravitational field is responsible for *forced* oscillations of the atmosphere—a condition of affairs very different from Sir Arthur Eddington's pulsation theory, which takes account of *free* oscillations in the atmosphere. The physical properties of such a system are dealt with and certain important effects are shown to correspond to observational data. Thus, since the amplitude of the oscillation is greatest at the equator and zero at the poles, it might be expected that the apparent velocity of the surface and the variation in luminosity would decrease with increasing latitude of the earth's direction—a correlation actually discovered in 1937 by Joy. Among the many explanations of the characteristics of the Cepheids may be mentioned that relating to the period-luminosity relation and the $P\sqrt{p}$ law. When accretion by the system has reduced the separation of the components to fusion into a single body, this body would be rotationally unstable if the mass ratio is less than 3 : 1, and stability could be restored only by the ejection of a portion of the main rotating mass. Regions of the star at very high temperatures would thus become exposed and a nova would occur. It is shown that under reasonable assumptions of surface temperature before and during the outburst, an increase in luminosity of 10–12 magnitudes would be expected. In addition, it is suggested that a large amount of atmospheric gases would stream out between the two main components at the time of fission, and this might finally be responsible for the shells of gaseous material which form the planetary nebulæ.

BULB FORMATION AND FLOWER PRODUCTION IN ONION PLANTS GROWN FROM SETS

By O. V. S. HEATH and M. HOLDSWORTH
Imperial College of Science and Technology, S.W.7

THE dependence of bulb formation in the onion on the stimulus of long days has been well established[1,2,3,4,5], and also the interaction of day-length with temperature[3,5]; a day-length just adequate at high temperature fails to induce bulb formation at low temperature, or leads to long delay. With regard to inflorescence emergence ('bolting') Thompson and Smith[3] recorded a large temperature effect but no effect of photoperiod, a lack of response attributed by Heath[5] to the limited range of day-length covered in their work. Heath concluded that conditions favourable to bulb formation (long days, high temperatures) are inimical to bolting and vice versa. In this communication an outline of the further analysis of this apparent antagonism is presented.

In a large factorial experiment we raised plants from sets (small bulbs) in which no inflorescence primordia were present at planting time (March 1942). Throughout the summer these plants were given 11½-hr. daily illumination at each of two temperature ranges (means 18° C. and 26° C. respectively). In early October half of each lot was transferred to 16½-hr. days (daylight supplemented with electric light). At the high temperature range (mean October–January 24° C.) in long days, bulbing began five weeks after transfer and then rapidly became general. No inflorescences appeared in this treatment. At the lower temperature (mean 14° C.) in long days, only 7 per cent of the plants had bulbed by ten weeks from transfer, and even at sixteen weeks when the experiment was ended only 40 per cent had produced bulbs. In this treatment, 7 per cent of the plants had produced inflorescences by ten weeks and 21 per cent by sixteen weeks. It is worthy of note that only one plant bolted *after* having been recorded as showing signs of bulb formation. Among all the plants remaining in short days (11½ hr.) only two, at the high temperature, formed bulbs and none showed inflorescences. The results are presented in Table 1. At the end of the experiment all the plants were pickled and were later dissected to ascertain the stage of development of the growing point. Data from the dissections are given in Table 2.

It is apparent that the plants grown at high temperature in either long or short days showed no signs of inflorescence development but were still in a vegetative condition; whereas at the low temperature in both day-lengths 65 per cent of the plants had initiated inflorescences. A difference, however, is seen, for whereas in the 11½-hr. days only $\frac{12}{65}$ of the inflorescences had scapes of more than 12·5 mm. in length, in the 16½-hr. days $\frac{51}{65}$ showed such scapes. The following conclusions are drawn from the data:

(1) At temperatures low enough to prevent or sufficiently delay bulbing, long days actually accelerate the emergence of inflorescences (Table 1 *B*, column 4).

(2) The action of long days in suppressing inflorescence emergence under conditions favourable to more rapid bulb formation[5] is therefore presumably an indirect effect connected with the bulb development that they promote.

TABLE 1. DEVELOPMENTAL DATA FROM TIME OF TRANSFER (OCTOBER 6, 1942) TO END OF EXPERIMENT (JANUARY 26, 1943).

	Weeks		11½ hr. day		16½ hr. day	
			High temp. (Mean 24° C.)	Low temp. (Mean 14° C.)	High temp. (Mean 24° C.)	Low temp. (Mean 14° C.)

TABLE 2. TERMINAL INFLORESCENCES (EMERGED AND INITIATED) BY JANUARY 26, 1943. (DATA FROM DISSECTIONS.)

	Scape length	1	2	3	4
% of plants with inflorescences	>20 cm.	—	—	—	21
	20 cm.—12·5 mm.	—	12	—	30
	12·5—0·78 mm.	—	38	—	14
	<0·78 mm.	—	15	—	—
	Total	—	65	—	65

(3) There is a direct effect of high temperature in suppressing inflorescence initiation quite apart from the accelerating effect on bulbing, for not a single primordium was found at the high temperature in either day-length, although bulbing in short days was almost negligible.

(4) The rate of initiation of inflorescences is apparently unaffected by length of day, since 65 per cent of the plants showed primordia in each day-length. (The alternative hypothesis, that initiation began sooner in the long-day plants but afterwards came to an end, is less acceptable. It seems unlikely that 35 per cent of the plants were inherently incapable of forming primordia; as for the possibility of initiation being prevented by bulb development in the long-day plants, the presence of unemerged inflorescence initials at the end of the experiment was quite unrelated to the presence or absence of bulbing.)

The acceleration of inflorescence emergence by long days (Table 1 *B*, column 4) is thought to be brought about, in part perhaps, by an observed increase in the rate of elongation of the surrounding foliage leaves, but mainly, by a great increase in the rate of scape elongation (Table 2). In this respect the effect of long days resembles that described for spring cereals[6]. All the evidence to date (including further work by Heath and Mathur) supports the hypothesis that bulbing prevents emergence of the inflorescence, and since foliage leaves are similarly affected[5] it appears that bulbing inhibits longitudinal expansion of all organs. (Sideris[7] records that the original root system begins to die at the time of bulb formation; new roots do not appear until about three weeks later in soil cultures.) It is remarkable that long days by promoting radial extension (bulbing) at moderate and high temperatures should suppress longitudinal extension, whereas at a somewhat lower temperature long days accelerate longitudinal extension. It appears that as the days lengthen in spring a race between the processes of scape elongation and bulb formation must often occur, the resultant incidence of bolting being determined by the diametrically opposed effects of long days according to whether the temperature is or is not high enough for rapid bulbing. To this opposition may be attributed much of the apparently erratic bolting of onions grown from sets in various seasons and localities. The suppression of bolting by high temperatures in the absence of bulbing is unlikely to be of importance in Great Britain, as temperatures are seldom high enough except in the long summer days such as favour bulb formation.

It must be emphasized that the above experiments were performed with sets, and the plants had therefore been exposed to long days in the previous year during their production from seed. A further experiment starting with seeds may therefore be cited, in which the day-length was maintained throughout at less than twelve hours. These plants formed no bulbs, but produced inflorescences after some eighteen months. Clearly, therefore, at no stage during ontogeny are long days essential either for initiation or emergence of inflorescences, unless indeed the particular variety of onion used for this experiment was characterized by an exceedingly low photoperiodic requirement for flowering.

The experiments here discussed and further work now in progress will be published in full in due course.

RESEARCH ON EARLY MAN IN BURMA

OF recent years it has become increasingly evident that so early as lower palæolithic times human culture was not the same all over the world, and that the dissimilarities probably resulted from differences in race. Even in such a small area as the continent of Europe, it is clear from a study of distribution maps of stone age cultures that in Central and Eastern Europe the stone industries differ entirely from those found in the west, and furthermore the two groups undergo quite different developments. Whereas central and eastern Europe can obviously be linked with northern Asia, the stone industries of western Europe show close affinities with the lower palæolithic finds of the African continent. Although skeletal remains of this early date are extremely rare, the few sure indications that have turned up also seem to point to the same connexions. Now a third region has been entered and we find there a series of industries closely allied with others from south-east Asia, but dissimilar to their contemporaries in northern Asia or in Africa.

The *Transactions of the American Philosophical Society* (32) includes a scholarly account of the work undertaken, which was (1) to study the pleistocene period in Burma and to establish a chronological sequence for the alluvial formations of the Irrawaddy Valley, and (2) to investigate any stone age industries discovered in the course of the above researches. Hellmut de Terra, well known for his similar work in northern India, was responsible for (1), Hallam L. Movius, jun., for (2). Supplementary reports on the pleistocene vertebrates and molluscs of the region are given by Edwin H. Colbert and J. Bequaert respectively. There is also a note on an investigation undertaken by de Terra in Java. The geological chapters include studies of the Irrawaddy basin and in the northern Shan Highlands, as well as comparisons with neighbouring areas in India, China and Malaya. Movius describes a series of industries (Anyathian) which appear in early mid-pleistocene deposits. They resemble the Soan complex of northern India, as well as industries found at a number of sites in Java. The Soan always has been considered to have been intrusive in northern India: it would now appear to have been an outlier from Burma. Movius also notes the similarity between the Anyathian and certain heavy industries from Choukoutien, but the typical smaller industries from this area have not been found either in Burma or in Java. The later Anyathian (late pleistocene) though showing certain so-called upper palæolithic peculiarities, is essentially an evolution of the earlier Anyathian, and this is clearly shown from a study of the development of a series of specialized tools made from an unusual material, fossil wood. An interesting collection of neolithic implements and pottery was also made and studied. The first two appendixes are mainly catalogues of the pleistocene vertebrates and freshwater shells found. But de Terra's note on his visit to Java raises again the vexed question of the date of *Pithecanthropus erectus* and that of the newly discovered human remains at Modjokerto. The latter apparently must be considered to be earlier in age than Dubois' find.

In this short note it is impossible to give any detailed account of these investigations. The authors have opened up a new field of study, both in the realm of quaternary geology and of prehistory. Obviously, an enormous amount remains to be done, but the foundations are here for the first time well and truly laid. M. C. BURKITT.

A GIANT CAMERA

AN article by Richard Haard (*Bell Lab. Rec.*, 21, No. 10; June 1943) describes the largest camera of its kind in the United States, this being installed in the Photocopy Department of the Bell Laboratories, making so many as eight hundred negatives a day. It was made by the Rutherford Camera Co. and has one of the largest lenses of its kind in the country—a Goertz apochromat with a 72-in. focal length. The camera also has three other smaller lenses, and all four are interchangeable. With this camera a negative 3½ ft. × 6 ft. may be made as easily and quickly as one 8 in. × 10 in. The photographer works inside the camera, in complete darkness except for a dim red light.

The new camera consists of two rooms with the lenses mounted in a sliding panel in the separating wall. One is a dark room that has a giant "plate holder", called the "camera back", running on a track on the floor that extends through the wall carrying the lens, and into the "light" room. In this latter room, the easel that holds the tracing to be copied runs on a carriage on the same track. The easel is of the vacuum type. The flanged edges of the glass cover fit against rubber gaskets when the cover is lowered, and the vacuum which is then applied holds the drawing flat against the glass face of the easel so that all curves will be accurately reproduced. After this the easel, which is pivoted at the front edge of the carriage on which it rests, is tipped up into a vertical position. It is equipped with piston devices that check its motion at the end of the swings so that tilting it up or turning it back is a simple and rapid procedure. Because of the height of the top of the easel carriage, which is half the length of the easel above the track, a bench 2 ft. high runs the entire length of the track to enable the operator to place the tracings on the easel. Two powerful arc lights on each side of the track near the lens provide illumination.

The "camera back" in the dark room is arranged for two widely different sizes of negatives. The vertical plate against which the paper is placed is perforated with fine holes, and a vacuum acting through them holds the paper flat. If the negative to be made is smaller than the perforated back, rubberized curtains are drawn from the top and bottom and from the two sides to block off all holes except those covered by the paper. Vertical bars control the two side curtains.

Four men form the normal operating crew of the camera. In the light room, a man at one of the work benches measures the drawing, and from the size of the print called for, calculates which of the four lenses should be used. Using a loud-speaking telephone system interconnecting the dark and light rooms, he tells the operator in the dark room the results of his calculation. Four horizontal scales run the length of the tracks in both rooms and are used in setting the positions of both easel and "camera back" in accordance with the size of the drawing and the amount of reduction required. One scale is marked for each lens. After the operator in the dark room has mounted the proper size paper on the "camera back" and selected the proper lens, he moves the "back" to the designated marking on the scale for that lens. In the meantime, another operator in the light room has placed the tracing in the easel, tilted the easel up, and moved the carriage to the scale mark given him by the operator who has sized the drawing.

After the dark-room operator has finished his operation, he looks through a small red glass window in the wall to the right of the lens, and as soon as he sees the easel is in place, he operates a switch that turns on the arc lights. He then rotates a filter into position in front of the lens to cut down all but a negligible amount of light, uncovers the lens, and looks at the faint image of the tracing on the sensitized paper. Using hand wheels at one side of the "camera back", he then shifts the vertical and horizontal position of the lens so as to centre the image on the paper. Following this, he removes the deep filter, or replaces it with one that will best bring out the lines on the drawings, and makes the exposure. He stops the exposure by turning off the arc lights, which also acts as a signal to the operator to place the next tracing in the easel.

The dark-room operator then removes his exposed paper and slides it through a chute to the adjacent developing room, where it is developed, washed, and fixed, and then placed on a glass-top under-lighted table for inspection. Any weak spots are brushed with ferricyanide so that they will print stronger. The negative is then passed through another chute to the washing tanks in the outer room. After the washing period, the prints are dried on the power-driven drier and then passed through the oiling machine. This spreads a thin film of oil on the back to make the paper more transparent, and thus to decrease the printing time. Any excess oil is then wiped off and the negative is ready for printing.

FORTHCOMING EVENTS

Saturday, September 18

British Rheologists' Club (at Loughborough College, Loughborough), at 10 a.m.—Discussion on "Rheology in the Hosiery, Leather, Shoe and Allied Trades".

Association for Scientific Photography (at the Middlesex Hospital, London, W.1), at 2.30 p.m.—Discussion on "Clinical Photography".

Saturday, September 18–Sunday, September 19

Association of Special Libraries and Information Bureaux (at the Royal Society, Burlington House, Piccadilly, London, W.1).—Eighteenth ASLIB Conference.

Saturday, September 18

10.30 a.m.—Annual General Meeting.

11.30 a.m.—Prof. J. D. Bernal, F.R.S.: "Positive Information Service".

2.0 p.m.—Symposium on "The International Rehabilitation of Special Library Services".

Sunday, September 19

10.30 a.m.—Mr. F. C. Francis: "The British Museum as a Special Library".

11.45 a.m.—Major Irving Newman: "The Organisation of American Photographic Information Services in Great Britain".

2.30 p.m.—Symposium on "The Co-ordination of Abstracting".

5.0 p.m.—"ASLIB: What it is Doing and What it Hopes to Do".

Wednesday, September 22

Institute of Metals (at 4 Grosvenor Gardens, London, S.W.1), at 3 p.m.—Thirty-fifth Annual Autumn Meeting.

Friday, September 24

Faraday Society (at the Hotel Rembrandt, South Kensington, London, S.W.7), at 10 a.m.—A General Discussion on "Modes of Drug Action".

Saturday, September 25

British Psychological Society (at Tavistock House, Tavistock Square, London, W.C.1), at 2.30 p.m.—"Education of the Adolescent".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Lecturer in Electrical Engineering—The Principal and Clerk to the Governing Body, Wigan and District Mining and Technical College, Wigan (September 23).

Physicist to the Radiotherapy Department—The Secretary, University College Hospital, Gower Street, London, W.C.1 (September 27).

City Electrical Engineer and City Lighting Engineer—The Town Clerk, Municipal Buildings, Liverpool 2 (endorsed 'City Electrical Engineer and City Lighting Engineer') (September 30).

Assistant to the Advisory Mycologist for the Yorkshire Province—The Registrar, The University, Leeds (September 30).

Chair of Social Medicine—The Secretary, The University, Edmund Street, Birmingham 3 (March 1).

University Lecturer in Anthropology—The Secretary of the Appointments Committee of the Faculty of Archæology and Anthropology, Museum of Archæology and of Ethnology, Cambridge (April 15).

POST-WAR FOREST POLICY IN GREAT BRITAIN

OF the making of plans there is no end, but the White Paper on Post-War Forest Policy* deserves study for a number of reasons. It is of intrinsic national importance; it will affect the pattern of the countryside of Great Britain, particularly in those regions where the landscape is not dominated by hedgerow and wayside trees; while the proposals constitute an interesting example of the development of an industry directed and to a considerable extent financed by the State, but making provision for private enterprise. Moreover, the White Paper gives a summary of the work of the Forestry Commission since it was set up in 1919. It is clear that, within the limitations of policy and finance imposed on it, it has done good work and deserves appreciation from the public.

It is important that Great Britain should have a sound forest policy. First, the two world wars have demonstrated beyond doubt that an adequate reserve of standing timber is a national necessity. Although the available supplies were not large, and to meet the emergency it has been necessary to devastate and disorganize this country's forest resources to a much greater extent than in other belligerent countries, the ability to expand the peace-time home timber production many times over has meant the saving of millions of tons of shipping in both wars, and in both shipping has been vital to victory. The development of air power will only underline this experience. Secondly, there is evidence that the British people are beginning to realize that the full use of land resources is the basis of sustained prosperity. Forestry is one of the necessary uses of land, and a sound forest policy will enable forestry to be integrated with agriculture and other land uses. Thirdly, there is much land in Great Britain suitable for the growing of the kinds of timber we need—mainly softwoods—and from an economic point of view better so used. Fourthly, the British people have great forest responsibilities throughout the Commonwealth, and this, the heart and centre, should give a lead in the proper organization and use of forest resources, both actual and potential.

A sound forest policy for Great Britain must meet certain requirements. It must provide adequate resources in the shortest possible time; it must be wide enough to bring all the benefits which forestry can give to rural development in its widest sense; continuity of aim and effort must be provided for; State and private efforts must be integrated, and provision made for the development of both; an efficient home timber industry to utilize the resources must be maintained and developed; provision must be made for the building up of the necessary scientific and technical knowledge and experience to carry out the policy, and this calls for a vigorous research policy and adequate education of personnel; and lastly, the type and design of the forest authority must be that best fitted for the fulfilment of its tasks. The proposals of the White Paper will be considered in the light of these requirements.

---

* Post-War Forest Policy. Report by H.M. Forestry Commissioners. (Cmd. 6447.) Pp. 114. (London: H.M. Stationery Office.) 2*s*. net.

The Report states that the forest area of Britain is about three million acres, or 5·5 per cent of the land area. This is one of the lowest percentages of any country in Europe, and moreover, a considerable part of it has been cut over for war purposes. Other industrialized countries have a much larger percentage under woodland; for example, Belgium 18·4 per cent and Holland 7·8 per cent. The White Paper proposes that a forest area of five million acres be built up in a period of fifty years, made up as to two million acres selected as the most suitable from the existing three million acres, and three million acres of new afforestation. It would appear that this area could be withdrawn from rough grazings over a period without seriously reducing food production. When this has been attained, about 9 per cent of the land area would be under forest, and the timber produced therefrom would ultimately provide about 35 per cent of our present consumption. From the information given, this is the minimum necessary to enable abnormal overcutting in an emergency of three or four years without serious and long-term disorganization of the forest resources, while from a peace-time point of view it does not aim at uneconomic self-sufficiency. It can only be considered adequate under intensive management. It is emphasized that planting alone is not enough, but that subsequent care and tending are essential. The policy to be followed in forest management is not discussed in much detail, although this is an important matter.

The proposals envisage that, during the first decade, 1,100,000 acres would be replanted or planted at a net cost of £41·2 million. This is called the "desirable" programme. An "intermediate" programme of 875,000 acres costing £32 million is also given. If the financial resources and trained personnel are available to carry out efficiently the "desirable" programme, it appears to be more in accord with the needs of the country. The estimated average annual cost of the "desirable" programme during the first decade would amount to less than 7 per cent of the cost of timber imports into Great Britain in an average peace-time year.

The White Paper rightly stresses the timber production aspect of forest policy, but it also deals with rural settlement, employment, and the recreational aspect through the medium of National Forest Parks. The amenity aspect is mentioned. It is noted, however, that smaller woods, and in particular shelter belts, are excluded from the dedication proposals to be referred to later. In certain upland parts of Great Britain there is need for the rehabilitation and extension of shelter belts in the interests of the pastoral industry, and this should be provided in the forest policy, although the work would have to be carried out in consultation with agricultural interests. Land put to productive uses has a beauty of its own, and the amenity value of woods should not be judged from their early stages; but within the limitations imposed by the timber needs of Britain, every effort should be made, both in the pattern of the forests and the species used, to ensure that they accord with the varying structure of our countryside.

The proposals are a long-term plan of investment by the State, the fruits, financial and otherwise, to be gathered in due season. The provision for its carrying out will depend on Parliament and ultimately on public opinion. Means should therefore be taken to ensure that the public is fully informed of the progress of the work by controlled access to forest areas, through the Press, publications, radio and cinema. Adequate publicity is essential for continuity.

The forest policy enunciated by the Acland Committee, which has been the basis of the work of the Forestry Commission since its inception, was impaired by two happenings. First, the Government reduced its grants in two periods of trade depression, while the part allotted by the Committee to private forestry was greater than could be undertaken in the economic and social circumstances prevailing, and no provision was made for the State to make good the deficiency. As regards the first point, it is to be hoped that future Chancellors of the Exchequer and chairmen of economy committees will appreciate that in periods of trade depression, capital investment by the State should be increased and not decreased, while the defect in the previous policy is removed in the present proposals.

It should be emphasized that practically all the timber which has been of such great value to Great Britain's effort in this War and that of 1914–18 was grown by private owners, and that our woodlands are still predominantly privately owned. Moreover, private foresters have, in the past, made important contributions to technical advancement. Britain was the pioneer in the introduction and trial of tree species from all over the world. This was done wholly by private enterprise, and the example and the results have been of great value to forestry development, not only here but also throughout the world. Further, many of the most important technical developments both in Britain and elsewhere have been made by private foresters. Unfortunately, the health and vigour of private forestry has declined, particularly since the War of 1914–18. The causes and their cure are mainly national and not forest, namely, the effects of taxation on rural properties and a feeling of insecurity which particularly affects forestry; but the forest policy should aim, so far as it can, at the resuscitation of private forestry, because it is capable of making our forestry a richer and more varied thing than it would otherwise be.

The White Paper proposes a scheme whereby private owners would 'dedicate' woods. This would involve an undertaking to use the land so that timber production would be the main object, to manage according to an approved plan, to employ skilled supervision, and to keep adequate accounts. In return for this and also for the continuance of the war-time control of fellings, the State would pay 25 per cent of the net annual expenditure when there was a deficiency, and provide private loans at current rates of interest. The scheme provides that all suitable forest land should be dedicated or in due course taken over by the State, land not properly used being dealt with first. The needs of the country necessitate that all suitable forest land be used for timber production. To discuss whether the terms offered are the best and most generous which should be made is outside the scope of this article; it will be in the national interest, however, if it is made possible for owners interested in forestry, small and large, to play their part in forestry development in Great Britain. The task is so large that all who can help are needed, and private enterprise can make a distinctive contribution.

One of the tragedies of the present abnormal overcutting is that the future of the home timber industry is gravely jeopardized. Nevertheless, it is useless to create forest resources without providing for their logging and conversion. The problem is referred to in the White Paper, and it is stated that consultations are proceeding. It is one of great difficulty, but means must be found to conserve and develop the available skill and knowledge of the industry's personnel in such a way that the industry can be readily expanded as increased timber supplies become available in the future.

To fulfil the tasks envisaged by the White Paper will call for personnel in all grades who have the requisite imagination, love of the countryside, scientific background and technical training, and who will have available to them the results of a well-conceived and vigorous research policy.

On the educational side it is important that the right kind of men be attracted and proper provision made for their training, which should not be on too narrow a technical basis in the case of the higher grades. When recruited, they should be encouraged by reasonable conditions of service, and leaders developed by devolution of authority according to capacity. No concrete educational proposals are made in the Report, but these are promised later; it is important that they be adequate.

The outstanding research problems are discussed. There is emphasis on technical problems rather than on the broad scientific fields on which these technical problems rest. It is probable that the development of private forestry will call for research in the economic field of forestry, but no reference to such is made. The principal new proposal in research organization is the creation of a forest research station at Alice Holt. This will involve the withdrawal of the Commission's research workers from universities. The creation of field research stations, suitably equipped, is to be welcomed, and all the principal forest regions of Britain should ultimately be covered, but such centres must be irrigated by streams of thought and ideas from the sciences and arts on which forestry is based. The universities are, or should be, the centres of such inspiration, and such forest research centres should be regarded as seasonal centres only, the research workers being based on universities. This proposal in the White Paper should be reconsidered.

In the provisional estimate of expenditure for the first decade, the allocation for education and research is less than 1½ per cent of the total expenditure. This is certainly not excessive.

The design of the forest authority should, on one hand, promote the efficient and vigorous carrying out of the forest policy, and, on the other, secure adequate contact with Parliament, the source of its funds, and the other departments of State concerned with rural planning and development. The latter will be more important in the future than in the past. A greater area of land will be drawn from other uses, and it appears likely that the countryside of Britain will be more consciously planned as a whole in future.

The White Paper does not propose any important changes in the present constitution of the Forestry Commission. An *ad hoc* authority independent of the Agricultural Departments is proposed. Experience indicates that this is essential to secure vigorous forestry development, but machinery will be necessary for co-ordination with other interested departments and bodies to ensure the integration of rural development as a whole. A single authority for the whole country is also proposed. As agriculture and planning in Scotland is under the Secretary of State, the question of a separate authority for Scotland has been raised. On balance, the advantages of a single unified service are substantial, but it is clear that there should be wide devolution of authority, both in the interests of forestry development itself, and to ensure adequate integration with the agricultural and other departments. The greater the effective devolution, the more certainly will forestry development accord with regional characteristics, physical, social and economic.

The Forestry Commission differs from the usual Government Department in design. It has certain advantages, but one of the drawbacks is that it has no ministerial spokesman, being represented in Parliament by one of its members. While not recommending it, the White Paper suggests that in future it might be represented by the Lord President of the Council, assisted by a committee consisting of the Secretary of State for Scotland, the Minister of Agriculture and the chairman of the Forestry Commission. It may be suggested that the Minister of Town and Country Planning should also be included. Whether this proposal is the best to ensure that forestry is suitably represented in Parliament, and secure, with other means, adequate co-ordination with other interested departments, is a matter for careful consideration before a decision is made.

EDUCATION FOR WORLD CITIZENSHIP

Social Studies and World Citizenship

A Sociological Approach to Education. By L. J. F. Brimble and Frederick J. May. Pp. xii+158. (London: Macmillan and Co., Ltd., 1943.) 6*s*. net.

IF civilization is to survive, a super-national organization will have to be set up in order to restrain the ambition and moderate the selfishness of competing national States. We can no longer afford political anarchy: the world is too small, industry too complex, science too powerful. Our experience with the League of Nations, however, has taught us that the problem is not to be solved merely at the organizational or institutional level. Federations, leagues, world governments will not function unless there exists a public opinion capable of sustaining and animating them.

The formation of the attitudes and mental patterns appropriate to the political organization of the modern world is obviously an educational problem. Rightly directed, the schools could solve it in one generation, but, unfortunately, the obstacles in the way are immense. For education is nowhere looked upon as a revolutionary instrument. On the contrary, it is everywhere closely harnessed to national purposes and its chief task is that of conservation—of guaranteeing cohesion and unity in society.

Yet, even within the existing framework, far more could be done than is done to foster in young people the qualities needed to make them good citizens of the world. Indeed, teachers of vision already do much to inspire in their pupils loyalties which transcend frontiers. It is urgently necessary that their experience be spread wide. In addition, many difficult questions remain to be discussed and explored.

Mr. Brimble and Mr. May intend their book—the first of its kind to be published in England—as a contribution to such discussion rather than as an authoritative and definitive pronouncement. It is not, perhaps, a brilliant, highly finished and polished book—indeed there are many evidences of hasty composition—but it is cheerful, readable and highly provocative. The authors deserve our gratitude for having done a modest job so well and for completing it at so appropriate a moment.

Among the early chapters are "World Citizenship" and "World Democracy". In them, the authors describe the numerous existing international organizations—economic, scientific, medical, financial, religious, etc.—which represent the organs of the embryonic World State. They briefly discuss, too, what is meant by the democratic way of life. To them, democracy involves social and economic duties and they see in it a dynamic which, of necessity, makes it super-national in character: social justice can be attained and maintained at home only if its benefits are made universal. The whole world must be safe for democracy if it is to be safe anywhere: isolationism is its enemy.

Having discussed the application of these ideas to education in general, the authors devote a series of chapters to a closer consideration of what they imply for the teaching of each of the major subject areas in the curriculum of schools—natural sciences, history, geography, etc. They believe that the new spirit "will not show itself by the addition or deletion of this or that subject, but rather will it be evident in the angle of approach and the method of presentation of subjects already in the curriculum". Since the democratic ideals are super-national, they think that the kind of teaching which turns out good democratic citizens of Britain will, of necessity, help to produce good citizens of the world.

This belief leads them to devote much attention to the kind of work best described as "Education for Democracy". They hope that civics will be taught, so that citizens will understand better than they do at present the structure of the government for whose actions they bear responsibility; they suggest that world history be included in the curriculum, so that young people may learn to rise above the love of their own nation to the vision of a developing world community; they recommend that the literary diet include samples (in translation) of the great classics of other lands and that its content be chosen so as not to stress ideals (for example, love and admiration of war and strife) which are inimical to democratic world fellowship; they stress the importance of teaching natural science with due regard to its social applications, so that young people will see in science a major agent of social change and become used to thinking of it in terms of human welfare.

The authors have certainly collected a great store of useful advice which teachers would do well to study. Their book is a mine of practical suggestions, all of which could be applied. To do as they say would greatly increase the efficacy of the work being done and make teaching more vital and significant. At the same time, the book is not free from ambiguities and even contradictions. A scientific reader, for example, may be somewhat perturbed to see so much attention paid to religious education: "The whole of our youth training", say the authors, "should have a religious as opposed to an agnostic background". One's disquiet is not entirely assuaged by the next sentence: "But such training must be based on rational observation and not on emotional feelings and mythical beliefs". It should not be forgotten that (in the words of Prof. J. K. Hart, quoted in the book) though "primitively religion stood for the wholeness of the group, now it often stands for the fractionating of the community, the group and even the individual". In addition, religious feelings are often associated with an attitude of complacent superiority towards men of other faiths, which is not the best foundation for real fellowship. Some of our more religiously minded politicians have not been entirely free from this defect in their public utterances.

One should also note that the theoretical parts of the book are, in general, weak and unsatisfactory. Often the authors approach really difficult and interesting problems and then sheer off. They talk about bias and propaganda, but content themselves by saying it can be avoided. They devote a chapter to "Sex Guidance as a Social Discipline", but do not go beyond giving the ordinary advice with little attempt at fundamental interpretation or at a discussion of the psycho-analytic approach to the problems of aggressiveness and war. They do not consider the obstacles which exist to that proper ordering of our internal affairs and that reshaping of our economic and social order which is the necessary preliminary to the establishment of a world society. There is no detailed discussion of the kind of education required to diminish tension and resolve conflicts of a racial, religious or ideological kind.

It would have been well, too, if more careful attention had been paid to American experience and research. The problem tackled in the United States is in some ways not unlike that which faces us in Europe: how to teach persons belonging to different racial, religious and linguistic groups to live together without fighting. Lastly, it would have been useful to list and to state clearly questions and problems susceptible to objective and scientific treatment.

On one major point, I must join issue with the authors. They urge the imperative necessity of selecting and teaching everywhere an auxiliary world-language. Scientific men do not need to be convinced about this: 'Babel' has indeed become a curse instead of merely a major nuisance, and 'debabelization' must be attempted. But the authors opt for Esperanto, which, in my opinion, has very little to recommend it; its close attachment to European roots and forms militates against its universal extension. Its defects are such that after sixty years of active and ingenious propaganda, very few people can use it.

In fact, there are two—and only two—possible world auxiliary languages. The first is Basic English. The other is Lancelot Hogben's *Interglossa*, which is even more rational and scientific than Basic, and is so simple that it can be learned by an intelligent person in one or two days. It has all the advantages of Esperanto and few of its greater defects.

These criticisms will not, I hope, keep people from reading the book: they are to be taken as an index of vigorous interest and of stimulation. The authors have tackled an original subject and have attempted to pioneer: the proof of their success is found in the amount of praise they arouse rather than in the amount of agreement they receive. How forward-looking and progressive they are can be appreciated only when their book is compared with, say, the Norwood Report on "Curriculum and Examinations in Secondary Schools". This is a dull, turgid and backward-looking document, but it represents, alas, an attitude widespread among persons who have much influence on our educational system. The Norwood Committee has little faith in "Civics", little use for "Social Studies", little interest in "Education for Democracy". It believes that the aims of education must be transcendent and has little hope that guidance can be got from "the provisional findings of the special sciences, whether biological, psychological, or sociological". So far as one can find out from its involved and rather muddy statements, it is even doubtful whether that Committee would agree with Brimble and May's fundamental assumption, which is that the major function of education is to promote the welfare of mankind.

It is against a background of this kind that "Social Studies and World Citizenship" is to be judged if its true value and worth is to be properly appreciated. One hopes it will have the success it deserves, and that it will serve to initiate the fundamental discussion which is so badly needed. J. A. LAUWERYS.

THE RISING TIDE OF SCIENCE

Forward with Science

By Prof. Rogers D. Rusk. Pp. xiv+308+v+24 plates. (New York: Alfred A. Knopf, 1943). 3·50 dollars.

THE impact of science upon society has, as all readers of NATURE will know, already been the subject of much discussion. On one hand there is the optimistic school of thought which prophesies that, if only we employ sufficient men of science and technologists and give them the position of authority in the State to which their indubitable talents entitle them, we shall find ourselves entering into an age of plenty. On the other hand there is a growing, though less vocal, apprehension that for all these good things there may be a price to be paid, and that vigilance will have to be exercised to ensure that moral and spiritual values which are vital to the welfare of mankind are not submerged in the rising tide. The possibilities and the dangers are obviously far more than national in scope, and it was not without interest that one approached this treatment of the theme from across the Atlantic.

"The present volume", so the preface tells us, "aims to fill a definite need in making recent developments in science understandable and meaningful. It was begun in the pattern of a previous volume which treated of modern achievements in physical science and their relation to human life, but with the rising tide of social revolution there emerged even more clearly the urgent need to show where possible what recent developments are of the greatest human significance to-day and how the wave of science is related to the present engulfing social tide." This is a considerable programme for a volume of little more than three hundred pages, two thirds of which are occupied with brief but quite excellent accounts of the latest developments of physics in its 'purest' and most theoretical aspects. It is obvious that, in so brief a space there can be no adequate discussion of the problems raised and, indeed, Dr. Rusk is not arguing; he is telling us. Nevertheless it is good to have both the possible benefits and the inherent dangers of this sudden uprush of scientific achievement into a morally unprepared world so objectively and so honestly set out, as they are in this volume.

Dr. Rusk is not only a physicist but also a student of philosophy (there is, perhaps, just a trace of professional condescension in his dismissal of the philosophical speculations of Eddington and Compton), and takes a rather wider view than the sheer laboratory mind, which is apt to be a little dazzled by the brilliance of its own achievements. "The wave of scientific and technical development upon which the world has been rushing forward", he writes, "represents both a glorious accomplishment and a grave threat. It embodies the utmost in promise for the future happiness, comfort and intellectual achievement of mankind, while at the same time it also threatens the most serious consequences of misuse, leading even to destruction and death." On one hand, "It is not a government committee or a government fund of gold in Washington that can guarantee security in old age and sickness and financial depression; it is science with its potentialities for production . . .". On the other hand, technology has placed enormous power in the hands of a few, partly by the means which it affords for conditioning the mass mind of a nation, and partly by the ease with which the few, armed with modern weapons, can hold down the many. "The unholy alliance between war and science which has made modern warfare possible has intensified the capacity of a dictatorship to make men fight, and the incapacity of a democracy, for no longer can a million effective men spring up overnight."

Further, in the opinion of the author the wave of science has precipitated, or at any rate coincided with, a revolutionary social movement. "The great masses of mankind from the farms of Kansas to the flats of New Jersey and from the steppes of Russia to the mountains of China are beginning to recognize the potentialities of the technical age in which they live and the fact that they have a right to help shape their own future." . . . "No longer can one expect to set up a beneficent static State such as Plato's Republic, and no longer can we expect the unmodified truths of Malthus or Marx to enable us to achieve a final satisfactory static state." In fact Dr. Rusk seems to think that stability is no longer a possibility.

To steer society safely through the uncharted rocks ahead and to justify his optimism (for the book, as its title "Forward with Science" implies, is on the whole optimistic) Dr. Rusk looks to the spread of scientific education among the masses, and to an evolution from within science itself of some moral sense to replace the religious idea of 'sin'. He also cherishes the belief that there is some esoteric relation between science and democracy. In fact he repeats this theme so often that one wonders whether he is not practising a form of Couéism, and hopes by saying it often enough to make it come true; especially as he shows himself fully aware of the fact that, however it may be with science, her half-sister technology sits openly in the market-place ready to bestow her favours on anyone who is prepared to make a bid for them. "Science", he concludes, "is a self-perpetuating movement which can scarcely be stopped. In totalitarian states it has been controlled for purposes of military aggression, and in democratic nations it has risen up in its might to combat totalitarianism. But a controlled science is not a free science, and the essence of science is to be free. Social planning may seek to control the impact on society, but it must not control the spirit of science. Indeed, a free science more than anything else can make social planning possible and workable. But this in turn implies a high technical and moral and social level, and such a level cannot be attained through soft living or soft education, of which there has been too much."

"Forward with Science" is not a great book—one would scarcely rank it higher than first-class journalism—but it is a thoroughly honest attempt by a physicist who has read widely, thought seriously and who has more than average skill in putting his ideas clearly before the average reader, to deal with problems of urgent importance. As such it can be commended to the attention of the rapidly growing circle of readers who are becoming concerned about the impact of the tidal wave of science on the social structure. There is much in the book which deserves anxious thought.

Although, following the lead given by the author himself in his preface, we have dealt mainly with the sociological chapters in the book, it may be added that between them, like the jam in a sandwich, there are some very well-written accounts of the very latest developments in atomic and theoretical physics. Dr. Rusk is unusually successful to conveying to the lay reader the essence of these outstanding achievements of modern science, without worrying him with details which would only confuse, without adding anything of real importance. We may add that the illustrations, with which the book is amply furnished, are the most pleasing we have seen for a long while.

In conclusion, there is one sentence in the preface which I hope Dr. Rusk will agree to modify in his second edition. It reads: "If the scientific and technical level of our nation is continually to rise, as it must *if we are to retain world leadership*, the achievements of science cannot remain only for the cloistered few." The words in italics are, of course, common form, and could easily be paralleled from articles and reports in Great Britain and no doubt in Germany, the U.S.S.R. and elsewhere, but has not the time arrived when men of science, at any rate, might come to regard their work not as part of an international struggle for world leadership but rather as a common service for the good of humanity as a whole? If not, the outlook for society is indeed bleak. I feel sure that Dr. Rusk will agree. J. A. CROWTHER.

ABSORPTION SPECTRA IN MEDICINE

Spectrophotometry in Medicine

Being the authorised translation of "Medizinische Spektrophotometrie" by Dr. Ludwig Heilmeyer. Translated by Dr. A. Jordan and T. L. Tippell. Pp. xiv +280. (London: Adam Hilger, Ltd., 1943.) 30*s*. net.

THE German edition of this work was published in 1933 by G. Fischer of Jena. The author, working at the Laboratory of Clinical Medicine at the University of Jena, had by then made substantial use of modern methods of spectrophotometry for investigating body fluids, and at the outbreak of the War was still publishing valuable work in this field. His book received scant attention in British and American journals, but as the subject-matter grew in interest and significance and a knowledge of spectrophotometric technique became more widespread, the need was felt for a translation. The book was naturally somewhat out of date in 1939 and it cannot be doubted that, but for the War, Heilmeyer would have desired to revise some of the chapters rather drastically for the English edition.

The translators were faced with a difficult problem. The symbols in use in spectrophotometry have now been agreed upon and differ from those used in the German original, and the newer ones have been used throughout the translation. The description of spectrophotometric technique has been discreetly brought up to date, and here and there useful footnotes on recent work have been added. The work as a whole, however, remains as it was written and the very careful translation deals faithfully even with some obscure passages.

It is necessary to emphasize that clinicians and research workers using this book will need to search the literature of the last ten years for themselves.

The work consists of six parts. The first deals with the theory and technique of spectrophotometry and is excellent. The second is concerned with absorption spectra applied to blood and hæmoglobin derivatives, and provides a very convenient summary of a difficult field. Part 3 covers the first breakdown products of hæmoglobin, and is a section which will need much revision and amplification in the light of recent work. The fourth part deals with blood serum and both normal and pathological serum pigments. Bilirubin and synthetic bilirubinoid pigments, as well as the lipochrome pigments, are reviewed, but there is no mention of vitamin A, concerning the determination of which in sera there is now a considerable literature. The next part discusses the spectrophotometry of urine, urobilin, urobilinogen and uroerythrin, together with urochromes A and B. Hæmoglobinuria and porphyrinuria are considered as fully as the state of knowledge in 1932 justified. There is finally a short section on bile, ascitic fluid and cerebrospinal fluid. The translation is ably and copiously indexed.

The chief virtue of Heilmeyer's book is that it unites a thorough knowledge of spectrophotometry with the systematic study of pathological material available in a university clinical laboratory. In this respect it is unique and indispensable. It shows convincingly how much has been achieved in the field, and it is greatly to be hoped that this translation will prepare the way for a new edition after the War. In the meantime the present issue can do much to promote co-operation between spectroscopists and pathologists. R. A. MORTON.

SCIENCE IN WESTERN SZECHUAN

I. PHYSICO-CHEMICAL SCIENCES AND TECHNOLOGY

By DR. JOSEPH NEEDHAM, F.R.S.
British Scientific Mission in China

IN the foregoing articles of this series* the attempt has been made to report to Western scientific men something of the remarkable efforts of their Chinese colleagues in a pre-industrial hinterland lacking all modern resources. The attempt is here continued with respect to the western parts of the province of Szechuan, lying between the Tibetan borderlands to the east and the Yangtze valley in Hubeh to the west.

The principal city of western Szechuan is Chengtu. When Chinese jokingly discuss which city of Free China represents the lost cities of eastern China, Chengtu is always analogized with Peiping; and it does indeed have the air of ancient city culture. It covers a very large area, much of the city wall still stands, and it is rich in old bookshops. It might remind the English visitor of York (for some of the Buddhist abbeys are reminiscent of any cathedral close) if it were not so flat, with willow-fringed canals not unlike those of the Cambridge fens. Chengtu has for many years been the home of the ('missionary') West China Union (Huahsi) University, the buildings of which, erected in semi-Chinese style on an admirable campus, are now by far the best of any university in Free China. This University has very hospitably accepted no fewer than four other universities (all originally 'missionary', now known as 'private', as opposed to State, or national, universities) as evacuees, namely, Chilu University from Shantung, Yenching University from Peiping, Nanking University from Nanking, and Ginling Women's College (the Chinese counterpart of Girton College, Cambridge), also from Nanking. The total number of students is to-day somewhat more than 3,000, of which two thirds are men and one third women. In general, it may be said that these private universities concentrate mainly on undergraduate teaching and less on the higher walks of research than some of the other Chinese universities, but the importance of a great centre of student life under comparatively good conditions of existence in these days should not be underestimated. Among the presidents of these institutions are some internationally known scholars, such as Dr. Mei Yi-Bao of Yenching, the translator of the philosopher Mo-Tze, and Dr. Wu Yi-Fang of Ginling College.

A good deal of fusion of the scientific departments of these Universities has taken place in practice, though theoretically they are still distinct. In general, research interest is concentrated on practical problems of importance to the community. Thus the chemists of Huahsi University (Profs. Roy Spooner and Chang Chuan) direct investigations on the indigo and natural dyestuff industry of the province, on gelatin emulsions with reference to the production of X-ray plates, on the properties of Chinese soapnut saponins, on electroplating, and on tanning, for which there is an elaborate experimental plant established on the campus. Here all kinds of improvisations, under Dr. Chang's initiative, have had to be thought of; all the machinery is made of local woods, and when emery wheels cannot be had, one imitates them by setting broken glass in a medium of tung oil. In Chilu University, Prof. Hsieh Yu is interested primarily in the active principles of indigenous drugs, especially anti-malarials. In Ginling University, Prof. Tai An-Bang, a colloid chemist, supervises work on soy-bean globulins (important for the production of 'casein' glue), copper insecticides, and tung oil polymerization. It will be seen that here, as much as, if not more than, in any other Chinese universities visited, research on immediate war problems is going on, just as in Britain. But the burden of teaching weighs heavily on the staffs of these Universities, and until it is lifted attainment of a high level of research can scarcely be expected. One of the most outstanding scientific men at Chengtu is probably Dr. Li Fang-Hsun, the physical chemist of Ginling University, whose work on ionic entropies, ionic volumes, hydration, etc., is widely known. So also is the work of Dr. Li Hen, the mathematician and astronomer of Huahsi University, a member of the National Academy.

One of Dr. Li Fang-Hsun's colleagues, Dean Wei Shich-Rjeng, an extremely capable organizer, has collaborated with the progressive director of education of Szechuan province, Commissioner Kuo Yo-Shou, in setting up a factory for producing school and simple laboratory apparatus. This goes out to eleven other provinces as well, and includes good chemical balances weighing to 1/5 mgm. and all imaginable physical and chemical apparatus and chemical reagents. The plant includes a glass factory. To illustrate the primitive conditions which must often be overcome, it was remarkable to see a dynamo for providing a low-voltage electric current for electroplating operated by hand, as no main current is available in this region outside the city. Mention may also be made at this point of a Popular Science Hall, planned along the lines of the Science Museum at South Kensington, but only just installed in some buildings of an old temple. It was pleasant to see in the garden stone models of the principal figures in solid geometry, with inscriptions in Chinese assiduously studied in the shade of the trees by small Chinese boy scouts.

The best applied physics and chemistry in Chengtu is probably going on in the experimental establishments of the Chinese Air Force Research Bureau, directed by Colonel Wang Tzu, but details cannot be given here for security reasons.

Turning now to a few words on the technology of the region, which is exceptionally interesting, China has in the Tzuliuching (lit. "Self-flowing Well") area an inspiration to her modern industrial chemists. For centuries back, so far that the memory of man runneth not to the contrary, there have been brine wells in this area, sunk by local methods using bamboo rope-suspended drills working for perhaps twenty years to complete one boring, and producing several sorts of brine, black, white and yellow. These brines are of different composition, and from them, by modern methods, partly in private factories, and partly in plants under the National Resources Commission, numerous important salts are separated (for example, salts of barium, boron, magnesium, lithium, strontium, bromine, etc.). Not many miles away, at Fivebridges, the Huanghai Industrial Research Institute (a privately supported organization on the same lines as the Mellon Institute at Pittsburgh, but in an entirely rural setting, ably directed by Dr. Sun Shioh-Wo and Dr. Chang Chien-Long) analyses these brines and works out new methods of separating their constituents.

---

*See NATURE, July 3, p. 9, July 10, p. 36, and July 17, p. 64, 1943.

The brine region is indeed nothing more nor less than an industrial area in the midst of a vast pre-industrial country and civilization. Needless it would be to point out the fundamental importance of such a source of salt in Central Asia so far from the sea-coast. The technique remains primitive to this day; a bamboo cable drops down the boring for two or three thousand feet and is wound up on a huge horizontal drum driven round by oxen. Steam and electric winding-gear is now, however, being introduced. But yet another circumstance is remarkable, namely, that the brine is associated with enormous amounts of natural gas, and one may see vast halls with hundreds of pans of evaporating brine each heated by a large burner connected with a boring. Still more extraordinary is the use of bamboo piping for conveying the brine from the wells to the factories over miles and miles of country. These bamboos are bound round outside with bamboo strips and cemented together with tung oil and lime; they stand a pressure of 80 lb. per sq. in. Unfortunately, bamboo will not do for water-supply in towns, as it is rotted by fresh water.

Such is ancient chemical technology in west China; the new has other features we must admire. Under the National Resources Commission, industrial plants have sprung up everywhere in Szechuan. In the sugar-producing area around Inwardstream (I garble-translate the place-names as usual), there are large works producing power alcohol from molasses for motor-vehicles; that directed by Dr. Chang Chi-Hsi is an example. Urea from human waste serves systematically here as nitrogen-source for culturing the yeast. Near Fivebridges there is an admirable low-temperature carbonization plant (the coal supply is difficult, seams being usually only 2 ft. thick over a wide area) directed by Dr. Huang Rjeng-Chi, and a wood dry-distillation plant directed by Dr. Gao Chang-Kung. Now the characteristic of all these plants is that they are usually built and operated by men of general chemical engineering training but without special experience, who went, as it were, into the wilderness and 'created' (the French idiom alone expresses it) the beginnings of industry, under the urge of war but with an eye to the peace. From the high lecture-hall of Wuhan University at Chiating, a lovely town at the junction of two great rivers tributary to the Yangtze, one sees in the far distance two things—a statue of Buddha 360 ft. high carved in the cliff, and on the other side a factory chimney. The social gospel of Confucian this-worldliness is conquering at last.

Wuhan University at Chiating, presided over by Dr. Wang Hsing-Kung, himself a chemical engineer, is housed partly in a beautiful Confucian temple, with its library occupying the shrine of the sage itself; but the physico-chemical departments are located in an old family temple with a charming loggia on the top of the city wall overlooking the river with the great Buddhist place of pilgrimage, Mount Omei, in the distance. Here Dr. Hu Chien-Shan (one of Prof. P. M. S. Blackett's most eminent collaborators) works and teaches; he has just completed a book in Chinese on cosmic rays. Head of the Chemistry Department is Dr. Wu Pao-Liang, the physical chemist, who has recently published an interesting work on omni-range electrical forces and static nuclei. He emphasized the isolation of scientific men in this remote spot in his need for up-to-date data on nuclear masses. The theoretical physicist is Dr. Chiang Rjeng-Shou (a former collaborator of Prof. E. N. da C. Andrade); he is directing the work of Liu Li-Ben on copper oxide rectifiers and that of Lo Wei-Kuang on the effect of temperature on elasticity in metals. In chemistry, Dr. Yeh Chiao investigates the active principles of indigenous drugs. While at Wuhan I had the pleasure of seeing a microfilm-reading machine arrive from International Cultural Service at Chungking (this deserves an article to itself) together with many microfilms. We got the machine working and the first films at which we looked were *Science* and *Journal of Nutrition* up to February 1943. The delight of these isolated men may easily be imagined. But nearly all the material so far coming in this way is from the American side, and on the British side we are only just belatedly beginning.

There is no doubt that at Wuhan University the scientific level is very high, comparing favourably even with the National Southwest Associated Universities at Kunming. Chiating, however, contains other institutions of some interest. We may mention the Polytechnic College, where courses are given in all branches of chemistry and engineering pertaining to light industry; for example, in agriculture, paper-making, textiles, leather and sericulture. The lonely location of all this region may be visualized by the remark made by the engineer of one of the National Resources Commission power stations, who said, as we stood at the door looking towards the Tibetan border mountains, "Remember that this is the last power plant until you come northwest to the Soviet Union across Central Asia six degrees of longitude west and three degrees north!"

Another academic institution of the first rank is Tongchi University, situated in the very small town of Appletree Rapids a hundred miles or so down the Yangtze. It was originally the German-Chinese University, and the atmosphere is still mainly German, though of course anti-Nazi. Its president is Dr. Ting Wen-Yuan, a younger brother of the famous geologist V. K. Ting. Its headquarters are in an extremely beautiful temple beside the river dedicated to Ta Yü, the legendary engineer who first established China's irrigation systems. Under the carved and gilded beams and roofs portraying the life of this great organizer and technologist, the students gather for special lectures or pass to and from their classrooms. I was privileged to be there on the annual day dedicated to Ta Yü's memory, and to address the students, after the usual ceremonies and a speech on the work of engineers in China by Dr. Ni Chao. Here at Tongchi the departments of physics and chemistry live but a struggling life, for as at Wuhan, their apparatus was much damaged by bombing and transportation from the east, but the engineering departments are flourishing. The University has its own power plant, and the students spend much time in assembling and erecting a large amount of plant brought up-river. There is United Nations collaboration here, for the professor of steel construction is a Pole. Particularly striking is the Department of Geodetics, Surveying and Cartography under the able Dr. Yeh Shwi-An, with excellent equipment; this has almost a monopoly of the production of Chinese surveyors and mapmakers.

The definitely religious veneration paid to the great irrigation engineer, Ta Yü, is of much interest. Some distance to the north-west of Chengtu there is a town called Kuanhsien, where may be seen what must be one of the most remarkable irrigation works of the world. A great river, the Min Chiang, issuing from the mountainous country of the Tibetan borderland, is there diverted at certain seasons of the year by movable dams and spillways into an enormous cutting through a hillside, forming thereby an artificial river which fertilizes 500,000 acres of first-class agricultural land by means of 1,200 km. of irrigation channels. But the striking feature of the work is that it was begun in 250 B.C. by Li Bing, then governor of this province, and has been kept up ever since. Moreover, the Chinese were not content to regard such works from a purely utilitarian point of view. With their characteristic ability to raise the highest secular to the level of the numinous, they built upon the outermost spur of the hill through which the river cuts, a magnificent temple to Li Bing, and farther up, in a scarcely less beautiful situation, a wooded hillside next the river, another one to his son, also an irrigation engineer, Li Erh Lang. Note the contrast: incense sticks glow in the front of Li Bing's temple, but in its second court are numerous models of the improvements it is intended to make to the irrigation scheme. So also in Li Erh Lang's temple, the engineers have their living quarters, and the shrine and courtyard of Ta Yü is the Water Conservancy Office. In the middle of all this ancient culture, all these exquisite buildings, Li Bing's latest successor walks about, a slide-rule sticking out of his pocket, and with a Manchester training—Dr. Chang Yo-Ling. The British Scientific Mission has had particular pleasure in transmitting some of his papers for publication in British engineering journals.

It would be a delight also to speak of the chemists and engineers in the arsenals in this part of China, of their initiative and perseverance in erecting and operating up-to-date plants in the midst of the wilderness, and of the clever use that has been made of natural caverns for the protection of war science laboratories and special up-to-date machinery. But for security reasons this cannot be done. No one, however, could say, after seeing what the Chinese have done in technology, both ancient and modern, that they are a people inapt for the scientific control of Nature. If modern science did not develop in their country, it must have been due to specific inhibitory social and economic factors, and certainly not to any incapacity of the people themselves.

The tragic feature in to-day's situation is the economic straits of Chinese scientific men, especially in the universities. The steeply rising cost of living has hit them very hard, and neither the special rice allowances of the Government, nor the staving off of the evil day by the gradual selling of all the family possessions down to the children's dolls, avail to provide them with even a moderate standard of comfort and to guard against malnutrition. But this must be the subject of a later communication.

FEEDING HORSE CHESTNUTS AND ELDERBERRIES TO POULTRY

By H. TEMPERTON

National Institute of Poultry Husbandry, Newport, Shropshire

THE commercial poultry keeper, faced with an acute shortage of concentrate feeding stuffs, has been compelled to exercise considerable ingenuity in finding suitable supplements to eke out his food allocation and so maintain a reasonable proportion of his pre-war numbers of stock. The same problem, although to a lesser degree, has confronted the domestic poultry keeper, who is allocated sufficient meal to furnish approximately half the daily food requirements of his birds. Thus a person qualifying for rations for only four birds requires an additional half-pound of dry food substance in order to provide a satisfactory daily ration for this number of stock. It is estimated[1] that the daily amount of edible waste in the average small English household is approximately one pound of fresh substance, or approximately four ounces of dry matter. The further daily requirement of four ounces of palatable and nutritive dry matter must, therefore, be derived from other sources. The poultry Press, adopting the principle that no potential food source, however small in quantity relative to needs, should be despised, has frequently suggested the nutritive possibilities of natural food materials and requested youth movements and other voluntary services to collect acorns, horse chestnuts and beech mast for stock feed.

Reference to the available literature provides little experimental evidence of the value and effects of feeding such natural food materials to poultry, and it was considered desirable to obtain timely information. The use of acorns as a food for laying birds has already been described[2], and the present article gives an account of experiences with the feeding of horse chestnuts and elderberries.

Horse Chestnuts

The chemical composition of horse chestnuts is very encouraging, the dry matter being similar to barley, as shown by the following analyses (Woodman[3]):

AVERAGE COMPOSITION PER CENT

	Dry Matter	Protein	E.E.	N.F.E.	Fibre	Ash
Barley	85·1	10·0	1·5	66·5	4·5	2·6
Horse Chestnuts (Fresh) ..	50·8	4·3	1·5	40·9	2·5	1·6
Horse Chestnuts (Dry) ..	81·2	6·9	2·4	65·2	4·1	2·6

A characteristic constituent of the nitrogen-free extractives is a glycoside, esculin (æsculin, æsculinic acid) $C_{15}H_{16}O_9$, which on hydrolysis yields esculetin (æsculetin, 6,7-dihydroxy-coumarin) $C_9H_6O_4$ and glucose. Horse chestnuts also contain the glycoside quercitrin (quercinetrin, quercitrinic acid) $C_{21}H_{22}O_{12}.2H_2O$, which includes the ω-desoxy sugar, *l*-rhamnose. On hydrolysis, quercitrin yields quercetin (meletin, sophoretin, quercitrinic acid, flavin) $C_{15}H_{10}O_7$.

Esculin is a saponin and produces the characteristic soap-like foam which is apparent when cooked horse chestnuts are masticated. A sweet flavour remains which later turns to a bitter after-taste due to the presence of *l*-rhamnose and of gallotannin (gallotannic acid), a further constituent of horse chestnuts. Gallotannin is largely hydrolysed to gallic acid during the cooking of the nuts. Klimmer[4] refers to deaths among poultry due to tannic acid poisoning following the feeding of horse chestnuts. It is unlikely, however, that this constituent was responsible, since in an experiment[5] carried out with laying pullets the daily dosage of birds with 1·12 gm. of gallotannic acid over a period of twenty-five days did not adversely affect health or egg production although the birds were costive.

Outline of experiment. Four groups each comprising four cross-bred pullets which were in lay were used for the test and accommodated in individual cages in a battery house. Horse chestnuts at the daily rate of ½ oz. per head were added to a ration consisting of 4 oz. of a balanced laying meal. Four forms of air-dried ground chestnuts were fed as follows:

Group 1. Raw chestnuts.

Group 2. Boiled chestnuts.

Group 3. Chestnuts which had been steeped in water for forty-eight hours prior to cooking.

Group 4. Chestnuts which were leached in warm water for forty-eight hours after cooking.

The various forms of chestnuts were mixed with the appropriate quantity of mash and fed as a wet feed. All four rations proved markedly unpalatable and no improvements in this respect resulted from the efforts to debitter the chestnuts fed to groups 3 and 4. Where the birds could discriminate, the particles of chestnuts were thrown out of the troughs and they only ate the meal portion. In groups 2, 3 and 4 where the chestnuts were cooked and mixed intimately with the mash so that the birds were unable to distinguish the individual components, the ration as a whole was left untouched. A new set of birds which had had food withheld for the previous twenty-four hours were offered the four rations. Although obviously hungry they refused to eat more than a preliminary mouthful.

The supply of horse chestnuts used for the test was made available through the industry of local schoolchildren. The nuts were collected soon after they had fallen from the trees and stored in thin layers on the floor of an airy shed and turned frequently. Despite these precautions, 50 per cent (a conservative estimate) became useless for feeding purposes due to fungal infections. These were sorted and so far as possible not used for feeding.

The unpalatability of the material used must therefore have been due to the substances inherent in the chestnuts, and on the basis of this experience point to the unsuitability of horse chestnuts as a poultry food.

Elderberries

Elderberries have been advocated as a supplementary food for poultry, fed either in the fresh state or dried for use in the winter as a scratch feed. It is obvious at the outset that owing to their high water content, no substantial quantity of concentrate feed is likely to be conserved by their use in a fresh condition since the extent of replacement is limited by the capacity of the fowl's digestive system. Moreover, it is doubtful whether it is worth drying the fruits in view of the excessive shrinkage.

Two species of elder are widely distributed in the British Isles, the common elder, *Sambucus nigra*, and to a much lesser extent the dwarf elder, *Sambucus ebulus*. Both species are credited with strong purgative properties, and cases of poisoning have been reported following the ingestion of berries from the dwarf elder.

Elderberries are known to contain a cyanogenetic glucoside, sambunigrin $C_{14}H_{17}NO_6$, which has been shown to be identical with the intermediate product mandelic nitrile glucoside (prunasin) formed in the hydrolysis of amygdalin. This would suggest that the use of elderberries as a stock feed involves some risk, more especially if included in a wet mash which is allowed to stand for any length of time before feeding, since enzymatic hydrolysis may proceed to the extent of liberating free hydrocyanic acid. Drying elderberries is said to reduce the toxicity.

Reference to the available literature indicates that the pharmacological effects are not very definite. Small quantities apparently purge animals and large intakes produce cardiac acceleration and severe emetic, cathartic and diuretic effects.

Outline of Experiment. Two groups each comprising six laying pullets were used for the feeding trial and housed in individual cages in a battery house. Both groups were fed a balanced mash at the daily rate of 4 oz. per bird. In addition, green unripe fruits and fully ripe black berries from the common elder were added in daily amounts of 1 oz. per bird for groups 1 and 2 respectively. At the commencement of the test the daily quota of berries were placed on the surface of the mash in order to obtain preliminary indications of their palatability. The ripe berries were relished by the birds, who ate them in preference to the mash, but the green fruits proved quite unpalatable and practically none was eaten. The fæcal portion of the excreta voided by the birds in group 1 became an intense purple colour twenty-four hours following the first feed and remained like this so long as the elderberries were fed. The physical consistency of the droppings and of the urine fraction was quite normal, however, and there were no indications of diarrhœa or diuresis.

After ten days the daily quantities of both forms of elderberries were crushed, mixed with the meal and fed as a wet mash. The ration containing ripe elderberries continued to be eaten readily, but the unpalatability of unripe berries was again marked, the mixed ration for group 2 being consumed reluctantly and part of the daily allowance invariably left in the troughs at the end of the day. This residue was mixed with the following day's food so that the effects of feeding material which had had favourable conditions for the hydrolysis of the glucoside could be observed. No harmful effects from either diet was noticed as a result of feeding the two rations for a period of thirty days. The birds in group 2 lost weight due to the subnormal food intake. Eggs which were laid by the experimental birds were broken and their contents examined. In every case these were described by independent co-operatives as perfectly normal in appearance and flavour.

It would seem from this limited test that no harmful effects to the health of laying birds or to the eggs they produce are likely to occur through the consumption of berries of the common elder (*Sambucus nigra*). Unripe berries are disliked by fowls and adversely affect the palatability of rations with which they are incorporated. Domestic poultry keepers with ready access to supplies may include ripe elderberries in the rations for their birds to provide variety and for condimental properties, but owing to their high water content it is obvious that no substantial saving of concentrate feed is likely to result from their use.

MEGATECTONICS AND MICROTECTONICS

By S. I. TOMKEIEFF
King's College, Newcastle-upon-Tyne

TECTONICS is a branch of structural geology concerned with the deformational structure of the earth's crust as a whole and of its major and minor elements. It was Nicolaus Steno who in 1669 laid the foundation of the science of tectonics, but it was not until the beginning of the nineteenth century that tectonics assumed the character of an inductive science. During its earlier stages, tectonics was concerned only with the larger features such as folding, faulting and jointing, but with the advent of the microscope in geology, smaller features of rocks came to be studied. The pioneer of microscopical methods in petrology was H. C. Sorby, whose series of papers published between 1850 and 1860 opened up a new line of research both in the mineral composition and in the texture of rocks. After 1860 the attention of petrologists was concentrated mainly on the study of the composition of rocks, and their textural aspects were treated only from a descriptive point of view. The study of larger features of the earth's crust, however, proceeded with increasing vigour and scope.

During the last few decades remarkable progress in the field of tectonics has been made along two distinct lines of advance. One—through the study of the large features of rocks, such as schistosity, flow banding, jointing, etc. (megatectonics); the other—through the study of smaller features of rocks, such as the disposition of the constituent minerals, cleavage, schistosity, etc. (microtectonics).

Megatectonics deals with the large-scale deformations of the rocks and their resulting structures. These large-scale features vary in magnitude from large folds, faults and overthrusts to banding, foliation, schistosity and jointing. Broadly speaking, all these features can be subdivided into those depending on the fluid or plastic deformations of rock material (for example, magma) or rocks (flow or flowage structures), and those depending on the rigid deformation (fracture structures). The main object in magatectonics is to find the relation existing between the structures (which are observed) and the deformations which gave rise to these structures (which are inferred).

Flow and flowage structures are found in igneous and metamorphic rocks. In the former they were usually produced while the rock was still in a liquid or plastic state (primary flow structures), and in the latter while the rock was in the state of solid plasticity (secondary flow structures or flowage structures). In the primary flow structures the principal structural elements are: (*a*) flow lines, such as linear arrangement of unequidimensional crystals, clots, inclusions, etc.; and (*b*) flow layers (bands and schlieren).

Fracture structures are found in rigid rocks that have been subjected to deformations exceeding the limits of a plastic flow. In certain cases fractures can even be produced in material undergoing plastic deformation, such as viscous magma prior to its crystallization. The principal fracture structures are joints and faults. Joints can be classified into contraction (cooling, desiccation), expansion, dynamic, dynamo-plastic, and compression joints. The dynamo-plastic joints are related to flow structures. Such joints are usually found in plutonic igneous rocks and they are classified into cross-joints (normal to flow lineation or flow layers), longitudinal joints (parallel to flow lineation and normal to flow layers), and flow joints (parallel to flow layers).

Numerous geologists, among whom may be mentioned Van Hise, Leith, Mead, Heim and Becke, have added much to our knowledge of megatectonic features. It was Hans Cloos, however, who was first to attempt a systematic study of flow and fracture structures in plutonic and volcanic rocks. His principal object was to co-ordinate the various structures in such a way that a reasonable deduction could be made regarding the movements which gave rise to these structures. Since his original publication in 1921[1] this work has been aptly summed up by himself[2], by his brother Ernst Cloos[3] and by R. Balk[4].

As applied to igneous rocks, megatectonics was called igneous tectonics (granite-tectonics, if applied to granites). Probably the most interesting and also the most difficult problem of igneous tectonics is that of the study of batholiths and related intrusive forms. In this study the two fundamental problems—the origin and the mode of emplacement of the rock—are closely related, and it is here that the method of Cloos seems to be most applicable. Numerous works dealing with this problem have been recently published. Among them one may single out the publications of the Committee on Batholith Problems (bibliographies, abstracts of papers), the series of papers published in the report of the sixteenth session of the International Geological Congress (Washington, 1936, vol. 1), and the works of E. M. Anderson and J. E. Richey on ring-dykes, cone-sheets, etc.

Great progress has also been achieved in the field of microtectonics. Ever since the introduction of microscopical methods into petrology the study of rock textures has been an integral part of this science. Texture, as we know, embraces three aspects of the smaller features of rocks: (*a*) crystallinity—the degree of crystallization; (*b*) granularity—the size of crystals; and (*c*) fabric—the shape and arrangement of crystals. Microtectonics is mainly concerned with the fabric of rocks. Certain rocks, such as gneiss or schist, show clearly a definite parallel orientation of crystals, while other rocks, such as granite or basalt, as a rule do not show any marked orientation of crystals. The first class of rocks have, therefore, been called structurally anisotropic rocks, and the second class have been termed structurally isotropic rocks. The new method of study developed by Sander and Schmidt has revealed that many of the structurally isotropic rocks exhibit a certain hidden anisotropy in the arrangement of their component crystals. This new method, based on statistical interpretation of quantitative data, opened up a new line of development in petrology, and at the present time we can already distinguish *compositional petrology*—a science dealing with the mineralogical and chemical aspects of rocks—and *structural petrology*, a science dealing with the arrangement in space of minerals in rocks relative to megascopical characters and field position. The principal idea underlying structural petrology is that the arrangement of minerals in rocks is due to certain movements which have affected the rock either during or after its consolidation. Structural petrology has also been called petrofabrics, petromorphology or petrogeometry.

The modern development of structural petrology is due to Bruno Sander, who in 1911[5] showed that in certain structurally isotropic rocks, such as quartzite, the grains, if studied by optical methods, are definitely orientated, that is, their crystallographic lattices show a preferred orientation. This internal orientation, in contrast to the dimensional orientation of grains (which quartzite does not possess), was called the space-lattice or crystallographic orientation.

The original approximate statistical method of Sanders was eventually placed on a rigid quantitative basis by Becke[6] and Schmidt[7]. This new method consists of determining the position of the optic axis (or any other standard direction) of a mineral grain by means of Fedorov's universal stage. This vector is plotted on an equi-areal projection. The plane of projection is usually chosen to correspond with some megascopical feature of the rock. A number of grains being thus measured and plotted on the diagram provides an assemblage of dots. After counting the number of dots per unit area, equal density curves (similar to contour lines on maps) can then be drawn. The petrofabric diagram thus prepared gives a statistical picture of the orientation of certain selected vectors of crystal grains (usually optic axes of uniaxial crystals or cleavage planes of mica) in relation to some selected megascopical feature or features of the rock, for example, plane of schistosity, cleavage, bedding or geographical orientation.

The application of this method to the study of rock fabrics has been described in great detail by Sander[8] and Schmidt[9]. Sander's book is inordinately obscure, partly on account of the intrinsic difficulty of the subject, but mainly because of the cumbersome method of exposition. It is full of new terms for which there are no adequate English equivalents and of which the meanings are unfamiliar to ordinary petrologists. English versions of structural petrology have been published by E. B. Knopf and E. Ingerson[10] and H. W. Fairbairn[11]. These two books, which in certain respects are complementary to each other, embrace the whole field of structural petrology, and give a very clear picture, so far as the nature of the subject will allow, of this intricate science, besides providing a complete list of references. The book by Knopf and Ingerson is wider in its scope and more gradual in its approach, while the book by Fairbairn is more detailed in a restricted field.

A novice may at first be discouraged by the intricacies of structural petrology and especially by its terminology; he may even be tempted to reject the whole of it as a piece of elaborate nonsense, a mountain made out of a molehill. However, this attitude of prejudiced criticism is unwarranted; in the past, many attempts to introduce new methods in science have initially met with scant approval. It nevertheless remains true that the methods of structural petrology are far from simple and that the interpretation of the data obtained is often ambiguous.

The technique of structural petrology falls into four successive stages. The first stage, collection and slicing of orientated sections, is quite a simple process. The second stage, the measurement on the Fedorov's stage, is a rather laborious and time-consuming process. The third stage, the preparation of petrofabric diagrams, is comparatively simple. The fourth and last stage, the interpretation of petrofabric diagrams, is really a difficult process full of snags and pitfalls. The problem which has to be solved is the deduction from the symmetry and density areas of the diagram of the direction of the movements which determined this particular rock fabric, and this is not easy.

Several types of rock fabrics can be distinguished: isotropic, anisotropic, homogeneous, inhomogeneous, depositional, deformational, superimposed, etc. Fabrics are also distinguished by their symmetry and by the pattern of density belts and density areas. Especially complex is the problem of dynamo-metamorphosed rocks, not only because the original fabric has been modified, but also because the movements affecting rocks in their solid state are highly complex. The chief difficulty, however, is that the nature of the orientating process is still a matter of conjecture, since we have no precise knowledge as yet of the internal mechanism of solid flow.

The science of petrotectonics is still very young; it suffers from growing pains and from an infantile rash of terminology; its methods are laborious; its principles still very uncertain. To some, the application of petrotectonics to geology may appear like the construction of an elaborate gun for the purpose of killing a fly. Nevertheless, there are definite indications that petrotectonics may eventually become an important adjunct of petrology and geology. Here are a few selected examples of its application.

Macrotectonics has its limitations—structurally isotropic rocks like some granites and quartzites are 'dumb' until subjected to petrofabric analysis. Schistose metamorphic rocks do not always reveal the direction of movements which affected them during their metamorphism. A number of microtectonic investigations on these types of rocks have thrown important light on the problem of metamorphism. The investigation by F. Coles Phillips on the tectonics of Moine schists[12] furnishes an admirable example. The mineral orientation in the Moine schists supports the hypothesis that the Moine metamorphism is of pre-Torridonian age, that the movement which produced the metamorphism acted along approximately south-west and north-east lines, and that the later Caledonian movement acting on north-west and south-east lines had apparently little effect on the fabric. On the other hand, the petrofabric study of the so-called "Tarskavaig-Moine" series[13] suggests that their fabric is related to the south-east movement.

The application of petrotectonics to problems of economic character has also been attempted with marked success. G. W. Bain, for example, has shown that various properties of marble, such as the maximum and minimum strength, ease of sawing, ability to transmit light, etc., depend on the orientation of calcite crystals in the rock. By means of petrofabric analysis Bain was able to select the most favourable direction for sawing slabs of marble in the position most favourable for transmitting light[14].

These are only a few examples of the application of petrofabric analysis to scientific and applied problems. Many others are on record in spite of the comparatively short period during which the development of petrotectonics has been in progress. It is safe, therefore, to predict an assured success for both microtectonics and megatectonics, especially if these two branches are closely combined and their methods and terminology standardized and simplified.

OBITUARIES

Dr. Aleš Hrdlička

BY the death of Dr. Aleš Hrdlička, which occurred in Washington, D.C., on September 5, at the age of seventy-four, the United States loses its leading exponent of physical anthropology, and anthropologists throughout the world a loyal and helpful friend. He was born of Czech parents who emigrated to the United States, carrying their young family with them, Aleš being the eldest of four boys.

Hrdlička's early life was a struggle, but by the age of twenty-two we find him a qualified homœopathic physician; later he took an allopathic degree. As soon as he qualified, we see him pursuing a practice which he continued with remarkable assiduity throughout life, that of observing, recording and publishing the interesting things he met with in his daily life. For Hrdlička, right from the beginning of his career to the end of it, was a quarryman, an assembler of building material, rather than a builder; he had a firm faith that master-builders would come along and find his materials of service. So it was when he became anthropologist to the Pathological Institute of the New York State Hospitals in 1896; he began measuring and recording the physical characters of the insane. At the beginning of the present century he passed from medicine to anthropology, becoming a member of the staff attached to the Department of Physical Anthropology in the U.S. National Museum, Washington. In 1910 he became curator of the Department and continued in that office until 1942; even then he did not retire but withdrew to the Smithsonian Institution, where he continued his labours until his sudden end.

During the period of his curatorship Hrdlička gathered personally, or acquired, representative collections of skulls and skeletons of men and anthropoids from their native regions in all parts of the world, aiming at giving each variety of mankind a full representation in the national museum, particularly those races which were, or have been, native to America. From time to time he issued reports on these collections, chiefly in publications connected with the museum. It was characteristic of him that he was never satisfied with reported discoveries of fossil man until he had examined the bones with his own eyes and measured them with his own callipers; no matter how out-of-the-way the site of discovery might be, in China, Java, Australia, Africa, Europe or South America, he made his way thither, held an inquest and returned with a documented report. The first of these reports appeared in 1913; the last and most valuable in 1930 (*Smithsonian Misc. Coll.*, vol. 83). He gave particular attention to discoveries of ancient man made in America, and seemed to take delight in reducing their antiquity to the lowest possible factor, and their type to that of the American Indian—in doing which his perspicacity was probably not much at fault.

Although Hrdlička grew up a fervid American, he retained a strong affection for the land of his birth, especially for its strong school of Czech anthropologists; they in turn were proud of him; on the occasion of his sixtieth birthday (1929), they celebrated the event by bringing out a Hrdlička volume of their publication *Anthropologie*. On the occasion of his seventieth birthday he was again honoured by having dedicated to him a volume of the *American Journal of Physical Anthropology*, to which colleagues at home and abroad contributed. It was fitting that this journal should celebrate the event, for it was Hrdlička's 'bairn'; he brought it into life in 1918, nourished and protected it until it grew into a hardy independence, and then handed it over to the Wistar Institute.

To aid in the celebration of this jubilee, Dr. D. Rubin de la Borbolla drew up a classified bibliography of Hrdlička's publications (*Boletin Bibliog. Anthropologia Americana*, vol. 2; 1939); between 1892 and 1938 they numbered 295. Clearly a review of such a literature does not fall within the compass of this notice; suffice to say that skull and brain, long bones and short, were subjected again and again to detailed report. In what may be called his field-work he centred his attention on the population of the United States, both living and extinct; on the changes produced by the arrival of millions of central Europeans in the first decade of the present century; the persistence of the British type in the descendants of early colonists ("Old Americans", 1925); more especially was his attention given to the American Indians, both to living representatives and to their predecessors, unearthed from ancient graves. No problem occupied his thoughts so continuously as that of the origin and homeland of this interesting race; his search for evidence turned his footsteps towards Alaska, and to the neighbouring region of Asia, which he finally concluded must be regarded as the cradle of the Amerind type.

In 1927 Hrdlička came to London to give the Huxley Lecture to the Royal Anthropological Institute and receive the Huxley Medal. In the spring of 1939 he again arrived in London, where he had arranged to give lectures at University College, and then to pass on to Russia, where important discoveries of fossil man had been reported. On leaving ship he had a sudden heart seizure (coronary thrombosis), lay for weeks in University College Hospital, made a surprisingly good recovery, gave his lectures and then made his pilgrimage to Russia.

In August of the present year I received from Hrdlička an autographed copy of what has proved to be his last book; it is entitled "Alaska Diary" (Cattell Press, Penn., 1943). Between 1926 and 1938 he made ten expeditions to Alaska, to study Eskimo and Indian, and to search for evidence bearing on the coming of the Amerinds; the "Diary" refers to the explorations made between 1926 and 1931. "These records", wrote Hrdlička, "have no pretense to any literary value, nor to any virtue aside from reality. They are just brief but faithful records of what befell or what was encountered by the writer."

With the "Alaska Diary" came a letter to me written by Dr. Hrdlička on June 23, some ten weeks before his sudden end. A few brief extracts from this letter will bring home to readers what kind of man he was better than anything I can tell them. "Future American histories of England", he said, "will be written in quite different, and much more honored and proud terms than were those of the past. May the English-Russian relations, also, continue and grow ever deeper. With those two realms going hand in hand, Europe will be effectually healed and restored, and so will much of the Old World; without it there would be misery and chaos." He took a rather pessimistic view of the future of his own subject: "I keep on, as formerly, and may yet see something accomplished even after the Alaska reports are off my shoulders. But conditions are rather disheartening; physical anthropology is in a deep trough. With anatomists weaned off from Anatomy and Anthropology, and the young would-be anthropologists impatient of sufficient preparation and so turning into flimsy statisticians, there are few chances in sight for a rejuvenation. . . . The basic reasons for the decline are plain enough. Those parts of anthropology that most appealed to the imagination and held most promise, have to a large extent been covered and failed to either satisfy or definitely solve matters. . . . But enough of this. If I have troubled you with it, it was with some faint hope that you might show me I am wrong, or getting old, or disgruntled, or something. As a matter of fact, I will the next minute be head-over-heels in happy and absorbing work on my old friend the tibia; and my head is full of plans and happy anticipations as to where I will go and whom to see after the war; and the seeing through of the three Alaska volumes is a real work of love." A. Keith.

Dr. A. H. Evans

Although it was published just before the opening of the present century, the volume on "Birds" by A. H. Evans, in Harmer and Shipley's "Cambridge Natural History", remains a well-used text-book. It is more readable than most text-books, it deals lightly and inadequately with structure (but then Beddard's work had appeared only the year before), and it concentrates upon the classification and particularly upon the appearance and habits of the birds themselves. This was almost to be expected, for Evans was essentially a field naturalist. In his schoolboy days at Durham, his interest in birds had been encouraged by Canon Tristram; at Cambridge, in the seventies of last century, it was confirmed by Alfred Newton; and the majority of his scientific contributions are records of observations in the field and faunal lists of areas he knew well.

Scotland gained much from Evans's frequent visits. To the fine series of vertebrate faunas of that country edited by Harvie-Brown and Buckley, he wrote, with the latter, "A Vertebrate Fauna of the Shetland Islands" (1899), and followed this with his own "Fauna of the Tweed Area" (1911); he also contributed occasional records to the *Annals of Scottish Natural History*. But his interests were not confined to local ornithology: with S. B. Wilson he described the birds of the Hawaiian Islands—"Aves Hawaiiensis" (1890–99); he wrote for the *Ibis* descriptions of his visits to South Africa and Australia with the British Association; he translated and annotated under the title "Turner on Birds" (1903) the rare sixteenth century "Avium Praecipuarum, quarum apud Plinium et Aristotelem mentio est, brevis & succincta historia" of William Turner, reputed father of British ornithology.

Evans took his share also in the conduct of ornithological affairs: from 1884 until 1889 he was recorder of the section "Aves" in the *Zoological Record*; from 1901 until 1912 he shared with P. L. Sclater the editorship of the *Ibis*; for some eight years he was guardian of Hickling and Horsey Broad for the owners; he was National Trust local secretary for Wicken Fen, and wrote an account of the Fen birds; he was president of the Berwickshire Naturalists' Club, and joint editor and vice-president of the British Ornithologists' Union.

These by no means exhaust the accomplishments of A. H. Evans, but they give the impression of a man of energy and activity, of learning and enthusiasm. Arthur Humble Evans was born in 1855, son of the vicar of Scremerston, Northumberland, and after graduating at Cambridge in 1879 (later he was awarded the Sc.D. degree) he continued there, teaching and tutoring in subjects which included English history and economics, for almost fifty years. When he was eighty-four years of age he published a "Flora of Cambridgeshire" and shortly before paid his last visit to a meeting of the Royal Society of Edinburgh. He died on March 28, 1943, having passed by little more than a month the eighty-eighth anniversary of his birth. James Ritchie.

Prof. F. Bacon

Engineers in many parts of the world who received their training at the University College of Swansea under Prof. Frederic Bacon, and the many others who came in contact with him through his varied activities, will learn with great regret of his sudden death, which occurred at Earlestone Common, near Newbury, on August 23.

Prof. Bacon, who was sixty-two, was the son of the Rev. J. M. Bacon, the scientific aeronaut. His first practical experience was obtained with Plenty and Sons, engineers, at Newbury. In 1899 he went to Trinity College, Cambridge, where he won an exhibition and studied under the late Sir Alfred Ewing. In 1902 he obtained first-class honours in the Mechanical Science Tripos. After further practical experience with Yarrow and Co. at Poplar and the British Westinghouse Electrical and Manufacturing Co. at Trafford Park, Manchester, he was appointed in 1905 to the teaching staff at the Royal Naval College, Greenwich, and later he also gave special lectures on the photo-microstructure of metals at University College, London.

In 1913 he was appointed professor of engineering in the University College of South Wales and Monmouthshire at Cardiff, and on the outbreak of the War of 1914–18 he organized the facilities of the Engineering Department for the manufacture of precision gauges required for shell manufacture. Later he served as lieutenant R.N.V.R. attached to H.M.S. *Vernon* in connexion with the design and development of paravanes, etc. Afterwards he was transferred to the Anti-Submarine Division of the Admiralty as technical expert in the experimental development of anti-mine and anti-submarine devices. In 1920 the chair of engineering was created in the University College of Swansea, and Prof. Bacon was appointed to this position, which he held until his death.

Prof. Bacon was a born research worker and investigated a number of problems in connexion with fuel economy, dust prevention, wind pressures, etc., but the work for which he will be best known was on fatigue, cracking and fracture of various materials. The most important papers on this work were: "Fatigue Stresses with special reference to the Breakage of Rolls" (*Proc. South Wales Inst. of Eng.*, 1930); "Fatigue and Corrosion Fatigue with Special Reference to Service Breakages" (*Proc. Inst. Mech. Eng.*, 1933), for which he was awarded the T. Bernard Hall Prize; "The Relation of Fatigue to Modern Engine Design" (*Trans. N.E. Coast Inst. Eng. and Ship.*, 1935). This last paper was in conjunction with two other engineers and was awarded the M. C. James Gold Medal.

A very large number of other papers and lectures on fatigue and allied problems were given to various engineering and technical societies, both in Great Britain and Germany; his last investigation, undertaken at the request of a Government Department, was on the notch sensitivity of certain materials under cyclic stress.

Prof. Bacon devoted much time to the leading engineering institutions; he took a prominent part in the formation of the South Wales branch of the Institution of Mechanical Engineers, was its secretary for several years and became its chairman. He was also a past president of the South Wales Institute of Engineers and served on the committees of the local sections of the Institutions of Civil and Electrical Engineers.

Although of a naturally reserved disposition, those who knew him best will remember his charm of manner as well as the unstinting interest he took in his students.

WE regret to announce the following deaths:

Prof. Frederick Barry, professor of the history of science in Columbia University, aged sixty-seven.

Prof. A. D. Bevan, professor of surgery in the University of Chicago, on June 10, aged eighty-two.

Mr. P. J. Haler, M.B.E., principal of the South-East Essex Technical College, on September 13, aged sixty-seven.

Prof. R. A. von Muttkowski, professor of biology in the University of Detroit, on April 15, aged fifty-six.

Mr. Colin F. Symington, of the Malayan Forestry Service, on September 9.

Mr. C. C. Willoughby, emeritus director of the Peabody Museum of Harvard University, on April 21, aged eighty-five.

NEWS and VIEWS

International Air Transport

A BROADSHEET (No. 208) entitled "International Air Transport", which P E P (Political and Economic Planning) has put forward as a contribution to the widespread discussions now taking place, is concerned with the extent to which the organization of international transport can be entrusted to international bodies. It reaches the main conclusion that there is a strong case for setting up an International Board for Air Navigation and for international public corporations for the operation of certain international services. A start should be made with corporations for Europe and for the North and South Atlantic. It is suggested that out of the large-scale emergency air-services which the United Nations will need to operate in the immediate post-war years to the shattered areas, distributing food and medical supplies, and carrying officials, medical men and technicians, a European airways corporation could naturally grow. Discussing future prospects, the broadsheet considers it certain that air transport will carry more and more international passenger traffic, cost and speed being two of the determinants. Much pre-war ocean travel in the first and cabin classes will be shifted into the air. Air mail is also likely to become more and more important.

The spirit of international co-operation will be essential if the opportunities are to be realized. Co-operation will be essential if air transport is not to continue a creature of nationalism, hampered by lack of freedom of the air and artificially stimulated by subsidies. Co-operation will be necessary to secure common technical standards. Unlimited competition among commercial operators is not likely to be tolerable, pooling agreements to mitigate the waste of competition will be insufficient, and some measure of international co-operation will be essential. This, however, involves reversal of many of the policies pursued in the past. The broadsheet visualizes a system of collective security in which an international police force plays a part and an international board for air navigation, following the precedent of the International Commission for Air Navigation established under the League of Nations. The possibilities of commercial co-operation have already been demonstrated by the International Air Traffic Association.

Reconstruction of the Social Order

IN a memorandum on the reconstruction of the social order, entitled "Peace and the Threefold Commonwealth" (London: Rudolf Steiner Publishing Co.; New York: Anthroposophic Press, 1943, 1s.), Mr. T. G. Jones gives an outline of the ideas of Dr. Rudolf Steiner as indicated more particularly in his books "The Threefold Commonwealth", "The Social Future and World Economy". The human social order is a threefold structure consisting of a body economic, the sphere of the State and a spiritual or cultural life. These are at present so entangled that none of them can develop fully on its own proper basis. If each of these parts of the social order is allowed to develop on its own proper ground it will bear rich fruit for the healing of social disease, and co-operation of the three parts to establish a threefold articulated healthy social order will then be possible. For this purpose economic associations for each industry and a Central Economic Council are suggested, and while the main task of Parliament would be to formulate and administer the code of rights, the economic associations would contribute from their surpluses to the economic support of the spiritual or cultural institutions.

The two main proposals in the memorandum are the allocation of a fair share of work between the several industries under the code of rights by determining mutually fair hours of labour, and the determination by the Central Economic Council of the total production of any one kind of goods and services. Each association would receive for its output a price comprising what it required to satisfy that part of the total needs of consumption for which it was responsible. To achieve this it would be necessary to fix a standard economic value as a unit of money, and each association would sell its product at a price representing the economic value or "organised labour value", a kind of quotient of work done for the elaboration of a natural product and the organization and division of labour by the human spirit. By distributing these values among the manual, clerical and supervising workers belonging to the association, again according to the consumption needs for which the association is responsible, among the lenders of capital and, through the Central Economic Council, among those for whom the workers in the industry could be held communally responsible in proportion to their needs, it is suggested the root causes of conflict between employers and employed would be eradicated. Other suggestions relate to the provision of funds for new or extended economic enterprise and the issue of money so as to ensure that it is a true medium of exchange and no more, and to prevent the money in circulation exceeding the economic values created.

The Kentucky Dam, Power House and Lock

THIS is a project of the Tennessee Valley Authority, and owing to the proximity of the site to the secondary zone of disturbance of the New Madrid earthquake of 1812, all structures forming part of the main dam were proportioned to resist seismic disturbances (*Earthquake Notes*, 14, Nos. 3 and 4; June 1943). The following seismic loadings were adopted: for mass structures of great rigidity an equivalent inertia force equal to 0·05 g. and for less rigid structures an inertia force varying from 0·06 g. to 0·10 g., based upon rational calculations of the dynamic action of the structure. The seismic increase in reservoir pressures was calculated by the Westergaard formula, using an earthquake acceleration of 0·05 g. For the two large retaining walls at the end of the earth embankment at each side of the river, special investigations were undertaken to establish the proper seismic loading. An extensive programme of shaking-table tests was conducted at Leland Stanford University by Prof. L. S. Jacobsen. On the basis of these tests an equivalent inertia force of 0·18 g. was applied to the conventional Coulomb wedge, the point of application being about 0·60 the height above the base. For structures sustaining hydraulic loads, the increase in overturning moment due to seismic effect was only 7 per cent, while the corresponding increase for structures such as retaining walls carrying earth loads was of the order of 35 per cent. Maps recently sent out by the State Geologist of the State of Missouri indicate large anomalies in both gravity and vertical magnetic intensity in Stoddard County, the locality of the great New Madrid earthquake of 1811. Whether there is any significance in the coincidence is not established, but the seismic precautions mentioned above do not appear to lack wisdom.

The Gas Industry in Great Britain

A BROADSHEET entitled "The Gas Industry in War-Time" (No. 210), which has been issued by Political and Economic Planning, brings up to date the report issued by P E P just before the War. It gives a concise factual account of the structure of the industry, including a note on the work of the Gas Research Board, to which gas undertakings representing 76 per cent of the gas output of Great Britain are now allied. Civil defence measures, man-power, the effect of the War on the distribution of demand, prices, fuel economy, coal supplies, gas quality, coke-oven gas, and trends in regard to coke and by-products are briefly surveyed. In regard to the last, six committees have been set up to investigate specific problems related to the replacement of imported by home-produced fuels, and to the most effective utilization of the latter in war-time, in particular the possibility of increasing the amount of liquid products—tar, creosote, benzene, toluene, etc.—obtained by high-temperature carbonization in gas-works and coke-ovens. Considerable progress has been made in the use of creosote pitch as a boiler and furnace fuel, although its high viscosity involves certain difficulties.

Public Health in Uruguay

IN a recent paper (*Bol. Of. San. Panamericana*, 22, 394; 1943), Dr. J. C. Mussio Fournier, formerly Minister of Public Health in Uruguay, gives the following account of public health in his country during the period 1938–42: (1) extension of preventive services; (2) better distribution of public health appropriations; (3) considerable increase of hospital beds and in hospital construction; (4) intensification of the campaign against tuberculosis. The Health Division, Bureau of Health Examinations and departments of vital statistics, industrial hygiene and school prevention have been very active and the campaign against diphtheria has progressed. The appropriation for the Ministry of Health has increased 32 per cent. The present Government has spent 1,847,500 pesos on tuberculosis treatment, 590,000 for mental patients, 3,170,000 for the Clinical Hospital, 2,774,000 for improvements in Montevideo and 1,675,000 for rural construction. In 1937 Uruguay had only 1,055 beds for tuberculosis, a number far below present needs, as there are about 2,400 deaths annually from this cause in that country. To-day, however, Uruguay leads all Latin-American countries in the number of beds devoted to that disease.

T. K. Sidey Summer-time Award

THE Royal Society of New Zealand invites applications for the T. K. Sidey Summer-time Award, consisting of a bronze medal and prize of £100, given for contributions to human knowledge by original scientific research in any of the following subjects: (1) the study of light, visible and invisible, and other solar radiations in relation to human welfare; (2) the general study of radiations of every kind. Such scientific research shall not be deemed to be limited to research in medical science. Primarily the award is to be made to a New Zealander or for work carried out in New Zealand, but the Council of the Society is at liberty to vary conditions and subject. Applicants for the award may submit either theses specially prepared or copies of published works. Applications should reach the Secretary, Royal Society of New Zealand, Victoria University College, Wellington, New Zealand, not later than January 31, 1944.

Mathematical Tables and Aids to Computation

ON January 1, 1943, there appeared the first number of a new journal, entitled *Mathematical Tables and Aids to Computation*. It is published by the National Research Council (Washington, U.S.A.), and is to appear quarterly. The subscription is three dollars a year. The editor is Prof. R. C. Archibald, chairman of the National Research Council's Committee on Mathematical Tables and Aids to Computation, to whose retirement from the chair of mathematics at Brown University reference was made in NATURE of August 21, p. 211. Some of the articles are bibliographical, such as one in the second number (April 1943) dealing with the various trigonometric tables with radian arguments. A valuable feature is a section on the description and location of unpublished tables. This, it is hoped, will not only help research workers, but also prevent useless duplication of costly effort. There is a section for queries and replies to them. The longest article in the first number is a list of eighty-eight recent tables, with reviews of the last fourteen and references to other journals where reviews of the first seventy-four can be found.

Earthquakes during June

DURING June 1943 thirteen earthquakes were registered strongly by the seismographs at Kew Observatory. The strongest of these was on June 9. The shock began registration with *iP* at 03h. 19m. 56s. U.T. and attained a maximum amplitude of 420 μ at 04h. 09m. 55s. U.T. on the vertical component at Kew. It is estimated to have come from an epicentre some 10,700 km. distant. This earthquake was registered at Stonyhurst at 03h. 20m. 40s. U.T., beginning with *eP*. Three shocks were registered at Kew and Stonyhurst on June 13. The first was by far the greatest. It recorded *iP* on all three components at Kew at 05h. 23m. 59s. U.T., apparently coming from an epicentre some 9,100 km. distant. The first recording was compressional and the maximum amplitude at Kew was 270 μ at 06h. 00m. 45s. U.T. on the N component. Stonyhurst recorded the shock at 05h. 24m. 10s. U.T. The other two shocks on June 13 were probably aftershocks from the same epicentre. The German News Agency reported a shock on June 12, recorded at Württemberg Observatory at 6.22 a.m., and believed to have taken place in the Eastern Alps, but this movement was not significantly recorded at Kew.

The United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the epicentres of three earthquakes in mid-June on the basis of instrumental reports received from observatories in America, Australia and New Zealand. The first was on June 13 at 5h. 11m. 44s. U.T. from an epicentre near 43° N., 142° E., which is near the central peak of Hokkaido Island, one of the Japanese Islands. The depth of focus was normal. The second was on June 14. The earthquake took place at 13h. 23m. 34s. U.T. at an epicentre near latitude 28·5° N., longitude 112° W., which is in the Gulf of California just south of the mouth of the Sonora River. The depth of focus was normal. The third earthquake was on June 15, occurring at 18h. 21·7m. U.T. from an epicentre near latitude 14·5° N., longitude 93° W., which is in the Pacific Ocean on the 100-fathom line west of the junction between Chiapas and Guatemala in Central America. This earthquake also had a normal depth of focus. The earthquake of June 20 was recorded at Kew and Stonyhurst. At Kew it recorded with *iP* at 15h. 38m. 04s. U.T. from an epicentre some 2,600 km. distant. It attained a maximum amplitude at Kew of 98 μ at 15h. 48m. 36s. U.T. on the vertical component. All interpretations and calculations are provisional.

Gift by Prof. T. D. A. Cockerell

PROF. T. D. A. COCKERELL, emeritus professor of zoology in the University of Colorado, will be remembered by many readers of NATURE as a frequent contributor of communications on biological topics. So long ago as 1920, he produced a useful and distinctive book entitled "Zoölogy: A Text-book for Colleges and Universities", which was reviewed in NATURE of December 23, 1920, p. 529. This was not an ordinary text-book of its time, for it catered for the needs of those who were not intending to specialize in zoology, and so included chapters on social life, the evolution of man, eugenics and sociology from the biologist's point of view. In its general approach it was perhaps in advance of much of the thought of its day. The book was re-issued from time to time, and Prof. Cockerell has now had prepared, at his own expense, an impression of a thousand copies which have been presented to the Board of Education in Great Britain. The gift will be much appreciated, and the volumes will no doubt contribute in no small measure to the growth of that biological outlook on man and his affairs which are necessary for the future peace of the world.

The Night Sky in October

FULL moon occurs on October 13d. 13h. 23m. U.T., and new moon on October 27d. 15h. 23m. The following conjunctions with the moon take place: Oct. 18d. 04h., Mars 4° N.; Oct. 18d. 14h., Saturn 2° N.; Oct. 23d. 07h., Jupiter 0·2° S.; Oct. 25d. 03h., Venus 4° S. The following occultations of stars brighter than magnitude 6 take place: Oct. 3d. 18h. 01·0m., 49 Lib(*D*); Oct. 8d. 18h. 43·5m., 19 Cap(*D*); Oct. 15d. 02h. 59·2m., μ Cet(*D*); Oct. 15d. 04h. 10·3m., μ Cet(*R*); Oct. 15d. 22h. 17·4m., *f* Tau(*D*); Oct. 15d. 22h. 58·6m., *f* Tau(*R*); Oct. 17d. 01h. 26·5m., γ Tau(*R*). The times are given for Greenwich and *D* and *R* refer to disappearance and reappearance respectively. Mercury attains its greatest western elongation on Oct. 10. It is a morning star, and at the beginning of the month rises at 5h., an hour before sunrise. At the end of the month it rises at 6h. 15m., 35 minutes before sunrise. Venus is a morning star and rises at 3h. 17m. and 2h. 37m. at the beginning and end of the month respectively. The planet attains its greatest brilliancy on Oct. 13. Mars can be seen in the constellation of Taurus in the evening and sets at 12h. 32m. at the beginning of the month and at 11h. 05m. at the end of the month. On Oct. 28 the planet is stationary. Jupiter, in the constellation of Leo, is a morning star, rising at 1h. 30m. at the beginning of the month and at midnight at the end of the month. Saturn can be seen close to Mars and is stationary on Oct. 9. At the beginning and end of the month the planet sets at 12h. 40m. and 11h. 10m. respectively. Times are given approximately for the latitude of Greenwich. The Orionid meteor shower is due about Oct. 18–21. The radiant is close to the star ν Orionis.

Announcements

PROF. EDWARD HINDLE, regius professor of zoology in the University of Glasgow, has been appointed scientific director of the Zoological Society of London.

THE following appointments and promotions in the Colonial Service have recently been made: J. D. Yeld, agricultural officer, Northern Rhodesia; T. Threlkeld (veterinary officer, Jamaica), senior veterinary officer, Jamaica.

LETTERS TO THE EDITORS

The Editors do not hold themselves responsible for opinions expressed by their correspondents. No notice is taken of anonymous communications.

James Prescott Joule and the Unit of Energy

A CENTURY has passed since Joule read his paper on the relation between heat and work at the meeting of the British Association at Cork on August 26, 1843. It is unfortunate that a difference of opinion has arisen about the correct pronunciation of his name and also of the word *joule* used to denote a unit of energy (ten million ergs or one Newton-metre). The "Oxford English Dictionary" gives *dzaul* as the pronunciation of the unit, where *au* represents the sound in the word *loud*. In "Webster's New International Dictionary" (1911) is found the statement: "The proper name is pronounced *joul* (*ou* as in *out*) and this is the correct pronunciation for the unit; but the incorrect *jo͞ol* [*o͞o* as in *fo͞od*] is very common especially in the United States." In "Chambers's Technical Dictionary" (first published 1940) we find the contradictory statements

joule, jool (Phys.). A unit of energy equal to 10^7 ergs.

(Named after F. [*sic*] P. Joule, 1918–89; name pronounced jowl.)

From boyhood I have been accustomed to the pronunciation *jool*, and was pleased to receive support for this from my colleague Sir D'Arcy Thompson, whose memories of the Royal Society of Edinburgh go back to the days of Lord Kelvin. He consulted Sir John Stopford, vice-chancellor of the University of Manchester, who replied on August 17, 1943: "I believe it is JOOLE and I never heard Jowle until comparatively recently when I think it came from the South. The family I knew in my youth insisted upon JOOLE and I think they were descendants". My friend Dr. George Green, of the University of Glasgow, was at one time private secretary to Lord Kelvin, and he writes (August 22, 1943): "The name Joule should rhyme with 'rule'. This is how Lord Kelvin pronounced it, and this has always been the pronunciation in Glasgow, as far as I can remember—by Prof. Gray (Senior) for instance." Prof. G. W. O. Howe (August 25, 1943) writes: "Some years ago I was troubled by the same question and I made enquiries—also in Manchester—and came to the conclusion that Joule and his relatives always pronounced the name 'joole'. I was pleased to learn this as I had always so pronounced it and regarded 'jowl' as a hideous mispronunciation".

I venture to suggest that the pronunciation 'Jowle' may have originated in Salford through the sardonic humour of local workpeople who, having in mind such an expression as 'cheek by jowl', spoke of 'Jowle's brewery'.

The pronunciation *joole* for the unit of energy (the joule) in the M.K.S. system of units has the advantage that it is immediately applicable in the French language—compare the words *boule* and *jour*. I am told by Mr. W. D. Oliphant, to whom I am indebted for much assistance in this question, that in the War of 1914–18 a French submarine (lost in the Dardanelles) was named *Joule*.

Seed Selection in Forestry

I HAVE been expecting to see a protest from one of our leading plant geneticists against the casual treatment of the subject of genetical research in the White Paper on Post-War Forest Policy (Cmd. 6447), but as it has not drawn their fire, I must presume that it has not come to their notice, and so venture to write as a forester with limited experience in this field. Right at the end of the section on "Ancillary Research", among the "Miscellaneous Investigations" of paragraph 383, is a bald reference to "work on the origin of seed, i.e., the effect of selecting seed of a given species from different parts of its natural range (a large number of comparative plots have been established in different parts of Great Britain)". The only other reference is in paragraph 395, where research on tree breeding is dismissed as insufficiently urgent to justify taking it up among the major projects after the War.

Now the White Paper envisages for Great Britain the afforestation by planting or sowing of some three million acres of bare land, and the effective management, which must also involve extensive planting, of a further two million. The trees planted out now will remain from, say, 40–120 years; we have complete control of the choice of stock to be used, but no possibility whatever of remedying during those long periods any mistake made in its genetic suitability. One might well marvel that, in view of the classical disastrous errors made on the Continent and the almost complete ignorance of the subject for the exceptionally varied conditions of Britain itself, this field was not made one of the major subjects of research from the very initiation of national forestry after the War. That it should continue to be viewed as a minor sideline is, to say the least, astonishing. There are often good grounds for suspecting that the genetic constitution of the stock is primarily responsible for the badness of the inferior tree crops so often met with in most parts of Great Britain; yet the collection and distribution of tree seed continues to be almost entirely haphazard. Surely it would be worth waiting even several years to make sure of procuring the best strains available for each district. Helpful as existing experiments on the differences between seed from different (again ill-defined) sources may be, the scale and execution is utterly inadequate to the importance of the subject.

An immediate step called for doubly urgently at the beginning of the present War was the selection and preservation of suitable stands on an adequate scale for seed production, but this is only one of the steps needed. It is almost superfluous to point to the example set us by several of the smaller countries of Europe in this matter, including some where planting is a far less common practice than with us.

Spray-Dried Rose Hip Powder

THE increasing interest that is being taken in natural sources of vitamin C in general, and in the extraction of this vitamin from rose hips in particular, suggests that some observations made by us on the production of a spray-dried rose hip powder may be of interest. In the autumn of 1942 it was desired to prepare a concentrated rose hip extract with high ascorbic acid potency, but a vacuum-evaporated extract proved to be somewhat unstable. In view of our previous success with the spray-drying of apples, plums and black currants, it was decided to apply the earlier technique to rose hips.

An extract of the fruit was made by boiling the milled hips with twice their weight of water for half an hour, the liquor being removed by hydraulic pressure. By this means a thick pectinous fluid was obtained, which on concentration gave a material with the following analysis :

Specific gravity ..	1·095
Ascorbic acid ..	219 mgm./100 gm.

No attempt was made to remove the pectic substances by enzyme action as the presence of pectin had been found, in previous work, both to aid the process of spray-drying and to assist in the retention of ascorbic acid. The concentrate was spray-dried in a semi-commercial Kestner machine. A smooth, free-flowing powder of very fine texture was produced without the slightest difficulty. Using an air outlet temperature of 85–90° C., a powder was collected which retained 5·1 per cent of moisture and 979 mgm. ascorbic acid/100 gm.—showing a negligible loss due to the drying process.

The powder was gas-packed in cans and after storage at room temperature for three months showed a loss of not more than 3 per cent in the ascorbic acid value. (The ascorbic acid determinations were carried out by the method of Harris and Olliver[1] and checked by the potentiometric method of Harris, Mapson and Wang[2].)

The hips used for the experiment were of poor quality, and very much higher figures should be obtainable with better samples of raw materials. It would appear that the production of such a powder might enable ascorbic acid to be added to certain solid food materials in this form.

Alleged Vitamin K Activity of Phthalic Acid

THE fact that several naphthoquinone derivatives and some related substances can replace the natural K-vitamins is most easily explained by assuming either : (1) that the prothrombinogenesis *per se* can be effected by several compounds, or (2) that the various vitamin K active substances are converted in the body into the same prothrombinogenic compound, which may be a substituted naphthoquinone.

Recently[1] it has been claimed that the vitamin K activity depends upon an oxidative biodecomposition of the suitably substituted naphthoquinones into phthalic acid. This compound was said to possess a perceptible although slight vitamin K activity, and the vitamin K activity of the 'diethyl ether' of phthalic acid was said to be high.

Potassium acid phthalate and diethyl phthalate have been tested for vitamin K activity in my laboratory. The method used was a modification of that of Dam and Glavind[2]; and the doses, fed to vitamin K-deficient chicks weighing about 300 gm., were 1, 10 and 100 mgm. potassium acid phthalate or 23 mgm. diethyl phthalate. The response was entirely negative. Under the same conditions menadione gave a considerable response in doses of 0·002–0·004 mgm.

Phthalic acid or diethyl phthalate can, therefore, not be the compounds which are responsible for the prothrombinogenic effect of naphthoquinones having vitamin K activity.

Whether substances showing vitamin K activity are converted by the animal body to phthalic acid is yet another question. At present, however, there seems to be little experimental evidence to support such a view.

This investigation was aided by the Josiah Macy, Jr., Foundation.

Purification of Mares' Serum Gonadotrophin

IN 1941, Rimington and Rowlands[1] described the production from pregnant mares' serum of a concentrate having gonadotrophic activity of 150–625 I.U./mgm., depending upon the activity of the serum, and equivalent, in the mean, to 73 per cent of the activity of the starting material. The process is suitable for large-scale operation. Slight modifications, details of which will be published shortly, have resulted in about a two-fold increase in the activity of the product at this stage, without affecting the yield.

Further purification has been effected by fractional alcohol precipitation at varying *p*H. Comparatively inert material, to the extent of 80–90 per cent by weight, can be precipitated by 50 per cent alcohol over a *p*H range of 5·0 and 1·5; in more acid mixtures precipitation did not occur or was incomplete. The active material separates on increasing the alcohol concentration of the supernatant fluid to 66 per cent. The temperature was maintained at 0° C. throughout ; no loss of activity occurred. The lower the *p*H of the mixture, to the limiting value of *p*H 1·5, the greater is the activity of the product. At *p*H 1·5 the products have assayed 11,750–12,500 I.U./mgm. and contain approximately 16 per cent hexose (orcinol method) and 8 per cent glucosamine. It was found that, whereas the hexose content of the products prepared at *p*H 1·5 and *p*H 5·0 respectively are in the ratio of 2 : 1, the ratio of their gonadotrophic activities is 12 : 1.

Experiments are proceeding to elucidate the chemical composition, electrophoretic behaviour and sedimentation velocity of our most highly purified preparations.

Silicates of the Perovskite Type of Structure

THE mineral perovskite, $CaO.TiO_2$, is known as the prototype for the crystal structures of a large group of compounds[1]; the unit cell is essentially cubic, but for most members distorted to various degrees in an orthorhombic, monoclinic, or triclinic manner. Hitherto the composition ABX_3 has been regarded as characteristic of this structure, where A and B are metal ions of the total valency six, and X is usually oxygen.

We wish to report that certain silicates also possess the perovskite type of structure, a fact which is believed to be new and of considerable consequence. They are merwinite, $3CaO.MgO.2SiO_2$ and its manganese analogue, $3CaO.MnO.2SiO_2$.

During the examination of basic electric arc furnace slags we found that a certain type differed in its X-ray diffraction pattern from the rest, and was closely related to perovskite. In contrast to normal finishing slags, this type had failed to 'fall' (that is, to disintegrate on cooling at 675° C through the transformation from β to γ-dicalcium silicate). The phases normally observed in falling slags, γ-$2CaO.SiO_2$, $3CaO.SiO_2$, CaF_2 and MgO, were absent from these samples; the absence of free magnesia in particular indicated that MgO would form an integral part of the new phase. The compound was identified as merwinite, dealing with which several publications have appeared recently[2,3].

The 'manganese-merwinite' was found by us by X-rays and is, to our knowledge, a new compound. It was obtained unexpectedly by firing 80 per cent β-$2CaO.SiO_2$ with 20 per cent $2MnO.SiO_2$ at 1,300° C. in hydrogen and cooling rapidly, in an attempt to determine whether a partial solid solution exists between these two compounds. The X-ray pattern of the fired product was the same as that of merwinite, but of a wider spacing. The composition of this phase is approximately $3CaO.MnO.2SiO_2$. The large Mn^{++} ion possesses a radius nearly midway between that of Mg^{++} and calcium ($Ca^{++} = 1{\cdot}06$, $Mn^{++} = 0{\cdot}91$, $Mg^{++} = 0{\cdot}78$ A.), so that it may also partly replace calcium, as is known, for example, in the garnets. The new compound attains a special significance, as it is liable to be produced in certain basic oxidizing slags.

The pattern of merwinite corresponds to a pseudo-cubic, but complex and somewhat distorted, unit cell, as revealed by the splitting of the main cubic lines into groups, and the appearance of additional reflexions. The lattice spacing of the ideal cube of merwinite is 3·76 A. against 3·81 A. for perovskite.

The fact of merwinite showing this type of structure seems important for the following reasons:

(1) The perovskite type of structure is highly accommodating in composition, and permits of a wide variation of relative and absolute ionic radii, without breaking down.

(2) No silicate of this structure type has, to our knowledge, been reported: a direct substitution in $CaO.TiO_2$ of Ti^{4+} by the small Si^{4+} ions (ionic radii 0·64 and 0·39 A.) would render the structure unstable (wollastonite $CaO.SiO_2$ differs entirely), but it becomes possible, if simultaneously some Ca^{++} ions are replaced by the smaller Mg^{++} or Mn^{++} ions and certain lattice-positions are vacated.

(3) The structure is not, as usually regarded, tied to the formula ABX_3. Further evidence for this is afforded by perovskite itself. In the lime-titania binary system it was observed that $CaO.TiO_2$ and $3CaO.2TiO_2$ are isomorphous, except for a slight lattice-distortion, a generally permitted feature of the perovskite family. Apparently a series of solid solutions exists of CaO in $CaO.TiO_2$, extending beyond 60 molecular per cent CaO and modifying, but not destroying, the lattice. The mechanism is again one of omission of ions from the lattice. Mg^{++} ions are also readily taken into solution. Thus, contrary to accepted ideas, the perovskite type of compounds may vary over a wide range of compositions from ABO_3 in the direction of and including A_2BO_4, covering merwinite if Ca^{++} and Mg^{++} are classed together.

The perovskite lattice consists essentially of a simple cubic lattice of Ca-ions with O-ions in the face-centres and Ti in the centre of the cube. The number of atoms per unit cell is $N = 5$. For merwinite, assuming the measured spacing 3·76 A., density 3·15 (value for natural mineral), mean atomic weight of $Ca_3MgSi_2O_8 = 23{\cdot}49$, calculation gives N in the order of 4·3 atoms, in close approach to perovskite, but again indicating a more open lattice (vacant positions). It is necessary to add that the actual merwinite unit cell will consist of a multiple of perovskite cells. Nine such cells stacked in a pseudo-cube, and containing three molecules (42 atoms) would form the smallest unit able to take an integral number of merwinite molecules and will constitute a probable true unit cell. The detailed structure remains to be analysed. However, postulating the basic SiO_4 tetrahedral groups, as for all silicates[4], a line of approach lies in modifying the known perovskite lattice so as to accommodate these groups.

The chief practical point arising, apart from the existence of the two compounds as such, is probably the high tolerance factor of the perovskite type of structure, which implies that merwinite is able to take into solution a variety of radicals from contacting substances (slag, steel), provided the atomic sizes and valencies permit. In basic electric arc furnace slags, we have frequently observed variations in line-intensities and spacings of the merwinite pattern, which no doubt correspond to partial replacements, each involving a modification, but not a breakdown of the lattice. Merwinite may be considered as possessing a 'sponge-like structure' in which CaO, MgO, MnO, SiO_2, TiO_2 can be replaced within limits. Its influence on the properties of the slag is pronounced; the non-falling and hard constitution of slags found to be merwinite is one example.

We have observed by X-rays the presence of merwinite or its isomorphs not only in basic electric arc furnace oxidizing and finishing slags, but also in basic open hearth slags.

This investigation forms part of a more comprehensive research into the constitution of steel works' slags and refractories.

Colour Microscopy in Ultra-Violet Rays

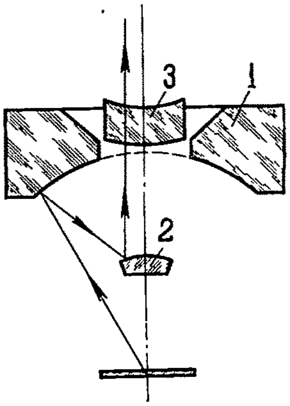
ULTRA-VIOLET microscopy has important advantages in the study of different microscopic objects[1]. In 1939 I suggested a new method of microscopy in ultra-violet rays, making use of selective absorption or reflexion of microscopic objects in the ultra-violet[2].

The first version of this method—the photographic one—is the following: a colour photomicrograph of a non-coloured object is taken in a way similar to that used in ordinary three-colour photography. The only difference is that to take the photograph three wave-lengths in the ultra-violet are used, whereas the reproduction of the three separation negatives is made with the help of the three primary colours in the visual, namely, red, green, blue. The hues of the details of such colour photomicrographs are given by the difference of densities of negatives taken in the ultra-violet, hence by the ultra-violet spectral absorption or reflexion curves for the corresponding parts of the object. The colours obtained are, of course, conventional; the image of the object is, so to say, shifted on the wave-length scale from the ultra-violet into the visible.

Some colour photographs taken in the way described are reproduced elsewhere[2,3]; they are illustrative of the possible applications of the method.

It is of great interest to construct instruments for direct colour vision in the ultra-violet without the use of the photographic methods. I have recently worked out and described two similar versions of a method for visual colour microscopy in the ultra-violet[1,4]. In the first, one each of the three ultra-violet wave-lengths excites one of the three primary colours on a fluorescent screen covered with a mixture of three substances, differing in the colour of their fluorescence, as well as in their excitation regions. In the second version, two rotating disks with three light filters each are used. Each filter of the first disk allows a certain part of the ultra-violet spectrum to excite a fluorescent screen and the corresponding filter of the second disk transmits one of the three primary colours of the white fluorescence excited.

The most essential part of the arrangement for colour vision and colour photography in the ultra-violet is the objective of the microscope. As is well known, it is not possible to realize achromatic objectives of large aperture for the ultra-violet with the use of the transparent lenses available for that region of the spectrum. Hence up to now only 'monochromat' objectives for monochromatic light had been devised by Rohr and Köhler[5]. The only attempt to use for this purpose the new reflexion optics was made recently by Johnson[6]. For colour microscopy, especially the visual kind, achromatic objectives are required. Therefore an objective of a new type based on reflexion optics (numerical aperture 0·50, $f = 6$ mm.) has been made by S. Gershgorin, P. Radchenko and myself following the suggestion of Gershgorin. The optical scheme is shown in the accompanying drawing. The reflexion objective, in contrast with the monochromat of Rohr and Köhler, allows the use of a broad spectral region; in consequence the arrangement is greatly simplified, more convenient light sources being used instead of the high-voltage spark of Köhler's microscope, and the expensive quartz monochromator being replaced by light-filters.



1, 2, MIRRORS; 3, FLUORITE LENS TO COMPENSATE FOR THE CHROMATIC ABERRATION OF COVER GLASS.

The method of staining of objects by organic dyes that are adsorbed on the tissues of the section, applied by biologists, is not highly selective enough and is usually characteristic only of a relatively large group of related substances. More refined investigations are made possible by the use of specific microchemical reactions that result in the formation of dye substances in the object itself. Unfortunately, most of the substances formed as the result of such reactions do not show any marked colour. Hence the search for microchemical colour reactions, especially for complex albumin compounds, is a difficult task. If, however, ultra-violet 'colours' typical for a great number of substances could be found, it is easy to visualize a new field of 'ultra-violet microchemistry', making use of the selective ultra-violet absorption of the products of the microchemical reactions. The development of this field which will follow the development and simplification of the microscope for visual observations in the ultra-violet will constitute an essential addition to the method of colour investigation of microscopic objects by means of the characteristic absorption of natural substances.

Reverberation in Small Glass Tubes

A CASE of what at first seemed anomalous resonance has been found here in the course of blowing small bulbs on the end of capillary tubes of "Pyrex" brand glass. If a piece of capillary tubing of this glass of between 0·7 mm. and 4 mm. bore and about 8 cm. long is melted at one end and a bulb of about 1 cm. is blown, during blowing and afterwards the tube will be heard to emit a note the frequency of which depends principally on the diameter of the bulb but also on the stem length and the bulb temperature.

If the bulb is thick-walled, the note may continue for a minute or longer; or if the bulb is held in the flame at about 700° C. the note may be sustained indefinitely, or at least until the bulb collapses. While the note continues, an appreciable efflux of air seems to take place from the tube.

Evidently the oscillation starts in a way reminiscent of the troublesome oscillations which make Clement and Desormes' classical experiment on specific heat ratios so difficult, and is sustained by reason of the fact that cold air sucked in during a half cycle is heated up and driven out at increased volume. Crudely, it may be supposed that the condition for sustained oscillation is that $\Delta T/T$ should be greater than $3r^2h/4R^3$, where ΔT is the temperature increase of the air, r and R are the radii of tube and bulb respectively and h is the length of stem. It is probable that the frequency is proportional to the rate of heat transfer from the hot bulb per unit volume of air, and hence inversely proportional to the radius. A bulb of 20 mm. diameter gives a low note near the limit of audibility, so that the production of audible frequencies is limited to tubes of small dimensions.

Relation between Dissonance and Context

According to Helmholtz's well-known theory[1], the consonance or dissonance of a chord depends on the extent to which its component fundamental tones and their overtones produce beats. Even a cursory study of the methods of musicians, however, and the experience of listening to music, make it seem possible that in actual practice the degree of harshness of dissonances varies considerably according to the way in which they are used and on their context of surrounding chords. A short experiment was planned to test this possibility.

A set of twelve dissonances was devised, of varying harshness and complexity, and each was provided with six different contexts or settings. Each setting consisted of two chords, one before and one after the test chord. In settings *A* and *B* a variety of chords were employed which had been chosen in the hope that they might produce some effect on the degree of dissonance of the test chord; in settings *C* and *F* the test chord itself was simply transposed one tone in sequence, passing the test chord downwards in set *C*, and, with otherwise identical notes, upwards in set *F*; in settings *D* and *E* arbitrarily chosen chords were employed, passing from complex combinations through the test chord to simple combinations in set *D*, and using the identical sets of chords taken in reverse order in set *E*.

The subjects of the experiment were forty-eight students who had some experience in psychological laboratory work; there were forty women and eight men. They were asked to listen to the groups of chords, which were played on the piano in the order *A* 1 to 12, *B* 1 to 12, and so on, and to assess the dissonance of the middle or test chord of each group on a scale ranging from − 3 (very dissonant) up to + 3 (very consonant). They did not find any difficulty in the task. It seems odd that positive assessments were used, though less freely than negative, but this is understandable to us, because, though all technically dissonances, some of the test chords formed very sonorous clangs of sound, and this may be one way in which Helmholtz's theory tends to break down. Two trial sets of chords were used to explain and demonstrate the aim and technique of the experiment to the subjects, and it was made clear that the experiment was not concerned with liking and disliking but only with consonance and dissonance.

The assessments for each chord in each of its settings were converted into scores by multiplying the totals by the corresponding ranks. Correlations were then worked out by the product-moment formula between the scores for each chord in settings *A* and *B*, *C* and *F*, and *D* and *E*. This gave thirty-six correlations, of which, according to the technique explained by Fisher[2], eight differed significantly from zero. These correlations are shown in the accompanying table. If there were no factor at work tending to make the chords sound equally dissonant (or consonant) whatever their context, we should expect no positive correlations. If there was a strong factor tending to make them sound quite different according to the context although they were the same chords, we should expect a large proportion of negative correlations. The fact that we find a small proportion of positive correlations enables us to draw the inference that there is some tendency for the chords to maintain their dissonance- (or consonance-) levels in spite of their changing contexts, but that those contexts have a very marked effect on the chords, tending to alter their level of harshness. The same conclusion is reached from the small magnitude of the correlations, only two of which were above 0·6.

Chord number	Pairs of settings correlated and probability of correlations					
	AB	*p*	*CF*	*p*	*DE*	*p*
2	0·50	<0·01	0·56	<0·01	—	
6	0·48	0·01	—		0·46	0·02–0·01
9	0·45	0·02	0·50	<0·01	—	
10	0·61	<0·01	—		—	
11	—		0·65	<0·01	—	

From these data it must be inferred that the dissonance of a chord depends even more upon the relation in which it stands to its surrounding chords than on the nature of the chord itself. The objection might be raised that the subjects were simply judging the dissonance (or consonance) of given chords in comparison with more (or less) dissonant chords on either side of them. This objection, however, is met by the results for settings *C* and *F*, which consisted of the test chord itself, transposed one tone up or down. In these settings there should, on the usual theory, be no contrasts of dissonance at all. It is perhaps surprising that settings *D* and *E*, which were arbitrarily chosen, should have produced fewer correlations than either *A* and *B* or *C* and *F*. It is clear that the experiment should be repeated with more adequate material composed by an experienced musician.

We are indebted to Mr. Joseph F. Simpson for calculating the correlation coefficients.

A Y-linked Inheritance of Asynapsis in *Rumex Acetosa*

Genically inherited asynapsis is sometimes met with in a number of plant species, according to observations made by various workers during the last ten years. The most remarkable cases were recently reviewed by Prakken[1]. In a number of the cases observed it was, however, not possible to say with any certainty if the lack of chiasmata at meiosis really was genically determined or not. One of these uncertain cases was observed by Yamamoto[2] in a Japanese male plant of *Rumex Acetosa*, but in *Rumex angiocarpus* I observed[3] asynapsis, which most possibly is of the modificatory type.

In the spring of 1939 I obtained a morphologically normal male plant of *Rumex Acetosa* ssp. *pratensis* from a locality in south-east Sweden. This plant was found to be characterized by a high degree of asynapsis. Although the pollen was almost completely sterile, a progeny was raised by crossing this individual with normal female plants from other localities. The high degree of asynapsis was also met with in all the male individuals of these progenies. The males were highly sterile, but the females were completely normal with a good seed setting.

As the first generation clearly showed that the asynapsis was genically caused, closer analyses of the inheritance of this disturbance were made. These analyses showed that the character is only met with in the male plants. This might, theoretically, be due to *Y*-linked inheritance or—as the number of male plants in the F_1 generation was as low as only six individuals—an *X*-linked recessive character. Closer analyses of the female hybrid individuals showed, however, that they were completely free from the gene for asynapsis. The cross hybrid female × normal male gave only normal males and females, the cross hybrid female × asynaptic male gave asynaptic males and completely fertile females, and these latter females crossed with a normal male also gave only completely normal males and females. On the basis of these results I regard it as most plausible to consider it as definitely demonstrated that the asynaptic gene in this material of *R. Acetosa* is located in one of the two *Y*-chromosomes.

According to Ono[4], Yamamoto[5] and others, the *Y*-chromosomes of *R. Acetosa* are completely inert as to sex-determining genes. The *Y*-linked inheritance of asynapsis in the present material shows, however, that the *Y*-chromosomes are not completely without genes.

A *Y*-linked inheritance of genes other than sex-genes has been previously observed in some few animals, but in plants only a gene suppressing the manifestation of an autosomal gene for 'variegated leaves' in Melandrium may, according to Winge[6], possibly be regarded as completely *Y*-linked.

Adult Education in Science

IN view of the attention now being given to the replanning of educational systems, experiences gained in Salisbury may be of value in directing adult education of the future along needed lines.

Initially, in 1940, an attempt was made by a number of university teachers to enable junior technical assistants of a Government establishment to complete gaps in their basic scientific training and so be able to continue their studies with greater facility at the end of the War. As time passed, however, it was found that enthusiasm was such that courses on advanced topics could be given successfully. These at once attracted a number of senior workers, who expressed the view that the more advanced discussions, particularly of rapidly developing subjects such as biochemistry, or molecular theories, were of great value to specialists, who feared that their outlooks might be becoming unduly stereotyped since, in many cases, their basic training had been imparted years ago.

I feel that this venture at adult scientific education in war-time is not only a success, but also that it is probably indicative of a widespread latent demand for more detailed information about recent scientific achievements.

It suggests that my pre-war "popular lectures" delivered, in conjunction with social service organizations, on "Science from the Easy Chair" lines were fundamentally misdirected efforts, and that the true function of adult education should be to keep alive, and develop, the enthusiasm for knowledge of those who realize the cultural dangers of specialized occupations, rather than to attempt to arouse faint interests when initiative is lacking.

Few, if any, other countries have so large a proportion of skilled technicians who, in the course of their daily work, have to become extreme specialists with but little opportunity to learn, once their basic training has been completed, even the broad lines of development of scientific thought, or to hear of modern discoveries of interest. Yet to many such specialists (witness those in the light electrical or textile industries) there may well come a time when fundamental scientific advances bring about the derangement of the whole of their prospects of beneficial employment.

If the adult education movement can enable technicians in industry to keep abreast of modern trends of scientific thought, it will be playing a more vital part in the life of the community than if, as at present, it is thought of as an 'escape' from a mechanized age. Unfortunately we are, in Great Britain, tending to mechanize science to the community by not disseminating widely enough the most modern scientific conceptions as they progressively develop in the light of new research.

A few public lectures in big cities, stimulating though they may be, are not enough. There are needed also planned courses at which are discussed current ideas which stimulate scientific thought and new discoveries of significance.

W. A. WATERS.

Salisbury. Aug. 8.

Archæology as a Science

IF all archæologists were of the calibre of Prof. Gordon Childe I could heartily endorse his opinions regarding the scientific status of archæology. But, alas, this is not the case, though no one, I hope, has a stronger belief in the value and importance of archæology, both from the historical and philosophic points of view, than I possess. Prof. Childe quotes as one of the methods of archæology "dispassionate observation". This desirable quality, which I understand is somewhat uncommon in any science, is not, I should have thought, exactly an outstanding characteristic in archæological circles. That, indeed, is my conclusion after many and sometimes exacting years of experience.

RESEARCH ITEMS

Archæological Survey of Pickwick Basin, U.S.A.

WHEN the dam at Pickwick Landing on the Tennessee River near Savannah was projected it became obvious that unless an archæological survey of the district was undertaken before the neighbourhood was 'drowned' much important information would be lost (Smithsonian Institution, Bureau of American Ethnology, Bull. 129. "An Archæological Survey of Pickwick Basin in the Adjacent Portions of the States of Alabama, Mississippi and Tennessee." By W. S. Webb, D. L. Dejarnette and others). Some nineteen sites were studied. Several of these showed the copper-galena complex of traits which connect them with other excavations in the Wheeler Basin. It would not appear that anything startlingly new has turned up, but an interesting series of flint implements, pottery and burials has come to light. These regional surveys will, of course, supply the material for a comprehensive account of prehistoric times in the U.S.A. when eventually the time is ripe for such a work to be projected.

Human Bartonellosis

IN a recent paper (*Bol. Of. San. Panamericana*, 22, 304; 1943) Dr. B. Mera of Colombia states that human Bartonellosis is an infectious disease of the most peculiar and constant epidemiology, manifested by fever and anæmia, by a typical skin eruption or by a combination of all these manifestations. The causal agent is *Bartonella bacilliformis*, a Gram-negative organism which is pathogenic for man and *Macacus rhesus*. Three foci of Bartonellosis exist at present in America, namely, in Peru, Ecuador and Colombia. In Peru, *Phlebotomus verrucarum* is the chief vector of the disease, while in Colombia several phlebotomi have been found, but the most responsible is still unknown. The only proved reservoir of the infection is the infected man with apparent or inapparent infection. The blood and reticulo-endothelial system are the structures most affected. At the present time the only effective means of control is by personal protection.

Relative Potency of Carcinogenic Hydrocarbons

SINCE the discovery of the carcinogenic action of 1 : 2 : 5 : 6 dibenzanthracene, 3 : 4 benzpyrene and 20 methylcholanthrene, these hydrocarbons have been used in laboratories in all parts of the world. It is often thought that methylcholanthrene is the most active, and dibenzanthracene the least active, of the three compounds. A thorough analysis of the sarcoma-producing action of the substances in mice has now been made by two American workers, Dr. W. R. Bryan and Dr. M. B. Shimkin (*J. Nat. Cancer Inst.*, 3, 503; 1943), using the statistical methods developed by Gaddum, Bliss and Irwin. The results show that although methylcholanthrene is the most rapid and dibenzanthracene the slowest in action of the three hydrocarbons, tumours are eventually produced with smaller doses of dibenzanthracene than of the other compounds. Much larger doses of benzpyrene are required for sarcoma production than in the case of either of the other substances. The experiments show conclusively that carcinogenic action follows the usual dose-response relationship found in other pharmacological actions. The probit of the tumour incidence is proportional to the logarithm of the injected dose over a fairly wide range of dose levels.

Protein Hormones of the Pituitary Gland

A VERY useful survey of our knowledge of the protein hormones of the pituitary gland is given in *Annals of the New York Academy of Sciences*, **43**, pp. 253–426 (Feb. 1943). Criteria of purity of these proteins such as crystalline form, homogeneity from electrophoretic, centrifugal, sedimentation and solubility measurements as well as constancy of biological activity are discussed. It is pointed out that if the biologist and physical chemist can agree as to what fraction of a preparation is "the substance" and what "the impurity", then the evidence from the physical chemist provides the best criterion of purity within the limitations of the experimental methods. Whether the pressor and oxytocic activities of the posterior lobe reside as an integral part of one large molecule, and the separate principles may be produced by cleavage of the mother molecule during extraction and purification; how far the chemistry has progressed of the anterior pituitary follicle stimulating luteinizing and lactation-initiating hormones, the latter, of course, prolactin, being the first pituitary hormone to be obtained in the pure state; the existence of "mammagen", the factor concerned with the growth and development of the mammary gland—these are some of the points on which evidence is reviewed and present theories are discussed.

Osteology of the Louvar

A DESCRIPTION is given of the skeleton of this fish by William K. Gregory and G. Miles Conrad (The Osteology of *Luvarus imperialis*, a Scombroid Fish: A Study in Evolution. *Bull. Amer. Mus. Nat. Hist.*, 81, Art. II, 1943). The specimen was caught off Cayo Corton Island, Florida, and weighed 200 lb. This is a rare pelagic fish, descending to considerable depths; it seeks its food, in all probability small planktonic organisms, by night, the mouth being small and the jaws without teeth. Its larval stages are exceedingly interesting, the fish undergoing several 'hypermetamorphoses' before attaining the adult form. The main plan of the skeleton consists of three longitudinal supports formed by the backbone and the interlocking bases of the dorsal and anal fins. The tail is large and powerful, with a specialized pivot vertebra at its root, permitting a wide sweep. The brain case is specially strengthened just in front of the first vertebra by extremely dense parts which receive the thrusts of the locomotor system. Otherwise the skeleton is delicate and fragile. The study is a detailed one and the figures are very well executed. There is a full discussion and summary of the structural and functional characters and of the phylogeny and classification.

Pedigrees of Polydactylism

IN more recent times the literature provides pedigrees of polydactylism in a few distinct families over a few generations. J. M. Odiorne (*J. Hered.*, 34, 45; 1934) has collected data in families all descended from a settler in New England in 1644. The pedigree involves ten generations and ninety polydactylous individuals who have an extra finger or toe on one at least of their extremities. The character is believed to be dominant with highly variable expression and penetrance. One wonders whether this weak penetrance observed in some human characters is not a result of polyploid interaction, as in the dahlia.

Dental Malocclusion in the Quintuplets

N. Ford and A. D. Mason (*J. Hered.*, 34, 57; 1943) show that heredity is an etiological factor in malocclusion, in which the jaws do not fit perfectly. Moulds of the dentition of the quintuplets have been taken annually and the time of eruption of the teeth noted. There was a difference of 25·8 per cent between pairs of quintuplets and 60 per cent between individuals in a population in regard to the order and time of eruption of the permanent teeth. This together with other evidence indicates that heredity plays some part in the formation of the jaws. A predisposing cause in the production of malocclusion appears to be the relative time of eruption of both temporary and permanent teeth.

Inefficiency of Iron Utilization

SOYA bean varieties differ in their ability to grow normally in low iron concentrations. M. S. Weiss (*Genetics*, 28, 253; 1943) has found that some varieties grow normally in low-iron cultures whereas others show iron chlorosis and finally die. On the basis of F_2, F_3 and backcross progenies between efficient and inefficient varieties, the author shows that one recessive gene *fe* causes inefficiency and iron chlorosis. Physiological effects of *fe* are higher *p*H, low-soluble iron, high total iron and low potassium contents.

Witches' Broom Disease of Cacao

THE cacao crop in Trinidad and Tobago is menaced with a serious witches' broom disease caused by the fungus *Marasmius perniciosus*. R. E. D. Baker and S. H. Crowdy (Mem. No. 7 Imperial College of Tropical Agriculture, Trinidad, B.W.I.; January 1943) have studied the symptoms and ecology of this malady, and their results are of interest to the general mycologist as well as to the plant pathologist. The fungus can attack vegetative shoots and flowering cushions of the cacao tree, giving variable symptoms. Sporophores are never produced upon green brooms, and only appear on dry brooms after five or six months. A short drought followed by heavy rain brings ideal conditions for sporophore production, and they may appear over a period of two years. Long periods of drought and continuous rain both have a depressing effect upon the appearance of fruit bodies, though they are generally more numerous in the wet season. The fungus is amenable to pure culture on several media, but no fructifications are then formed, even though the organism is homothallic. Spores are liberated mainly at night, when temperatures fall to between 85° F. and 57° F.; their ability to cause the disease has been demonstrated by successful inoculation with pure cultures. Infection with mycelium appears to be incapable of inducing the malady. This fact greatly facilitates control, since brooms removed from infected trees in May and October need not be collected and burned. They are innocuous if left scattered upon the ground.

A Tuned Null Detector

AN article by F. B. Anderson (*Bell Lab. Rec.*, 21, No. 10; June 1943) describes a new tuned null detector which has been designed to eliminate volume adjustment entirely, compressing a volume range of over 100 db. into a variation of the reading of a simple milliammeter, and reducing tuning to a very simple operation that does not require the use of calibration charts or curves. The basic element of the volume-control circuit is a pentode feedback amplifier with an input-output characteristic in which, for inputs less than 40 db. below one milliwatt, the plate current remains essentially constant at its maximum value, but as the input increases above -40 dbm., the plate current decreases, becoming essentially zero at an input of 0 dbm. This characteristic is secured by connecting a diode rectifier between the plate and grid in such a way that as the input increases above -40 dbm., a certain portion of the plate current, rectified by the diode, will increase the negative bias of the control grid and thus reduce the plate current. The grid-to-plate voltage gain in the region of 0 dbm. input approaches unity, so that several stages may be cascaded for input ranges in excess of 40 db. The detector is designed for operation at 1 kc. or at any frequency between 3 and 150 kc., and to permit the single tuning control to act over this entire range, an eleven-point six-gang switch is provided that divides the total frequency range into sub-ranges by switching in different sets of coils and condensers in the output circuit of each stage. The detector may be operated close to the driving oscillator without experiencing cross-talk. The sensitivity is about the same as that obtainable with earphones and a heterodyne operating at its highest sensitivity. The simple tuning and the complete freedom from volume adjustments obtained in this detector make it a measuring instrument that is decidedly superior to the auditory method under many conditions.

Resolution of the Telluric Bands ω_1 and ω_2

A SHORT note by A. Adel (*Astrophys. J.*, 97, 190; 1943) announces the resolution of the carbon dioxide bands at 2·01 μ and 2·05 μ in the solar spectrum. The rotational structure of the bands is clearly revealed, the separate lines being so much as 6 A. apart since alternate lines are forbidden by the selection rules. The rotational distribution corresponds to a mean temperature of $-18°$ C. for the carbon dioxide mass above Flagstaff, Arizona, at noon in January.

Configuration of Glycosides and Sugars

A NEW method for determining the configuration of glycosides and sugars, depending on the alkaline degradation of phenylglycosides, is described by E. M. Montgomery, N. K. Richtmyer and C. S. Hudson (*J. Amer. Chem. Soc.*, 65, 3; 1943). It was found that β-phenyl-*D*-glucoside and β-phenyl-*D*-galactoside are readily degraded by the action of hot aqueous potassium hydroxide to *D*-glucosan $<1,5>\beta<1,6>$, and *D*-galactosan $<1,5>\beta<1,6>$, respectively, while α-phenyl-*D*-glucoside was unaffected and α-phenyl-*D*-galactoside was attacked only very slowly under considerably more drastic conditions. The action of hot alkali on aromatic glucosides has long been known to cause hydrolysis, but most investigators seem to have assumed that the non-phenolic product was either glucose or its decomposition products. It is pointed out that the reactions studied resemble the anhydride formation in *cis*- and *trans*-dicarboxylic acids, and a similar relation to the groups in the glycosides leads to the same configurations as those previously assigned on other grounds.

ROYAL SOCIETY OF CANADA

ANNUAL MEETING

THE annual meeting of the Royal Society of Canada was held at McMaster University, Hamilton, Ontario, during May 25–27. The scientific sections of the Society held their meetings in the Science Building of the University and the general meetings took place in Convocation Hall. The president of the Society, Prof. J. B. Collip, presented the medals at the evening meeting on May 25. The Flavelle Medal was awarded to Prof. B. P. Babkin, research professor of physiology at McGill University, for his outstanding work in analysing the secretory mechanisms of the digestive glands. Prof. John L. Synge, professor of applied mathematics in the University of Toronto, received the first award of the Henry Marshall Tory Medal for outstanding contributions to applied mathematics; and the Willet G. Miller Medal, also awarded for the first time, was presented to Prof. Norman Levi Bowen, distinguished service professor of petrology in the University of Chicago, in recognition of his contributions to geology. Following the presentation of the medals, Dr. Collip read his presidential address on "Science and War". After briefly reviewing the part played by science in former conflicts, Dr. Collip emphasized the important contributions of physicists, chemists and other men of science in the present War. He dealt in some detail with aviation medicine and the co-operation between the men of science and the armed forces in solving many of the problems which modern warfare presents. He referred to the recognition and support that scientific workers are now receiving as an integral part of the war effort, and pointed out that much of this research work is producing results that will be equally important in the post-war period.

A further feature of the meeting was the symposium, held after the dinner on May 26, on "Medical Investigations as Applicable to the Armed Forces", at which Surgeon Captain A. McCallum, medical director-general of the Royal Canadian Navy, spoke in general terms of the organization for research in this service and of the work already accomplished. Surgeon Commander C. H. Best, director of the Royal Canadian Naval Medical Research Unit, gave a more detailed account of some of the results achieved in connexion with nutrition, night-vision and similar problems. Brigadier J. C. Meakins outlined briefly the medical research going on in the Army, and Group Captain J. W. Tice, director of Medical Services (Air), spoke of some problems of interest to the Air Force in particular. This was followed by Squadron Leader K. A. Evelyn, who discussed in further detail many of the special problems in aviation medicine, at the conclusion of which he showed a special moving-picture film entitled "Oxygen". This film was shown as a feature, permission for which had been specially granted. It was prepared under the auspices of the Associate Committee on Medical Research of the National Research Council for use in training enlisted aircrews in the essentials of physiology and the effects of high-altitude flying, pointing out the importance of the special precautions required.

Prof. J. K. Robertson delivered the presidential address in Section III (Chemical, Mathematical and Physical Sciences) on "The Role of Physical Optics in Research", in which he reviewed the discoveries into the nature of light, atomic and molecular structure and in astronomy which have resulted from the application of physical optics in spectroscopy, interferometry and diffraction. This historical account was followed by an address on "Chemical Reactions of Excited Atoms" by Dr. E. W. R. Steacie, and a paper on "Molecular Spectra and their Applications" by Dr. Andrew McKellar, who spoke particularly of applications in astronomy. Thirty-eight papers were presented to the section, the majority of which were read by title. Owing to the pressure of war work, few physicists and chemists were in attendance, but mathematics and astronomy were well represented. Among those papers which were read, mention may be made of a few of some general interest. Prof. Lachland Gilchrist and J. W. Britton gave an account of further experiments on the use of drill holes in electrical methods as an aid to the location of mineralized bodies and rock structure. Dr. J. A. Pearce announced the orbital elements of *H.D.* 222107 λ Andromedæ as revised on the basis of recent measurements and also the orbital elements of the spectrographic binary *H.D.* 34333. A paper of particular interest was given by Dr. L. M. Pidgeon on the production of light metals, in which he reviewed the methods for the separation of magnesium and the difficulties which had to be overcome. He gave an account of his own experiments, which resulted in the present method used in obtaining large quantities of magnesium metal in Canada since the outbreak of hostilities. Dr. H. F. Manske and L. Marion reported the isolation of eight alkaloids from *Lycopodium annotium* L. Several papers were presented by Dr. Paul E. Gagnon and his co-workers, among which mention may be made of one in which the isolation of some new sulphamides was announced. Perhaps the most interesting paper presented to the section was one of those given by Prof. E. F. Burton, in which J. H. L. Watson showed how stereoscopic photographs had been taken with the electron microscope, and exhibited several examples. This new technique enables one to view the objects photographed so as to bring them out in three dimensions, thus adding depth to the pictures and revealing new features in the structure of smoke and metallic particles. At the conclusion of the sectional meetings, Prof. T. Thorvaldson was elected president of the Section for the year 1943–44.

In Section IV (Geological Sciences), Prof. M. B. Baker gave the presidential address and spoke on "Gold and Iron Prospects in Canada". This address was followed by sixteen papers on various geological investigations. Among these, Dr. E. A. Hodgson delivered a very interesting paper on the "Rock Burst Experiments at Lake Shore Mines, Kirkland Lake". He outlined the programme of the investigations carried out since 1939 and gave some of the results already obtained. Equipment has been designed to pick up, amplify and record the small sub-audible snaps which occur in a rock under pressure and which increase in number as the pressure increases. The records of a severe rock burst which occurred on January 29, 1943, show conclusively that the method clearly delimits the area under pressure to within a hundred feet or less. So far, attempts to predict bursts as to time have not been successful; but it is hoped that further work will result in some measure of time prediction.

Prof. G. B. Reed, president of Section V (Biological Sciences), spoke on "Wound Infections and Local Chemotherapy". This paper dealt with the treatment of wounds with the sulpha drugs and emphasized the necessity of applying the drug as soon as possible after the wound had been inflicted in order to obtain the greatest benefit. Fifty-six papers were presented to this Section, many of which will appear in scientific journals. Space permits the mention of the two invited papers only. That by Dr. Babkin, on "Secretory Mechanism of the Digestive Glands", contained a survey of the work of his laboratory on this subject. Briefly, it may be stated that the investigations have established that the mucous, demilune and myoepithelial cell groups of the submaxillary gland each have a separate innervation, and that the surface epithelium cells of the gastric mucosa and the mucoid, peptic and parietal cells of the gastric glands are under independent nervous or humoral control. The conclusions to be derived from this work were stated and further analysis of the secretory function of the digestive glands given. The second paper, by Prof. G. W. Scarth on "The Mechanism of Frost Resistance", contained an account of the modes of frost injury to plant cells and of the protoplasmic changes which accompany frost-hardening. He also discussed how the different hardening changes afford protection. The new president of this Section is Prof. H. S. Jackson.

At the general meeting, Monsignor Olivier Maurault, rector of the University of Montreal and a fellow of Section I, was elected president of the Society, and Prof. J. K. Robertson was elected vice-president.

DAVID A. KEYS.

HERMIT CRABS FROM THE JOHN MURRAY EXPEDITION

DR. E. F. THOMPSON has published some interesting facts in the report referred to below* of collections obtained by the John Murray Expedition. The stations at which the Pagurids were taken are confined to the Gulf of Oman, the south Arabian coast, the Gulf of Aden, the East African coast, the Zanzibar region and the Maldive area, that is to say to the coastal regions and the two Gulfs.

The littoral and shallow-water forms are related to those of the rest of the Indo-Pacific region. The deep-water forms may be divided into those living at mid-depths, which have considerable affinity with those of the North Atlantic, and the only truly abyssal form *Parapagurus pilosimanus,* which occurs at great depths around the edges of every ocean basin in the world. Nothing is known of the life-history of this species. It has always been recorded as housed in a typical zoophyte growth. In the present collection this was not the case; a number of different shells were used, the most frequent being Ianthina. The zoophyte house begins around a shell, and the author has found in two specimens examined from the North Atlantic that this basis was also on Ianthina.

Paguropsis typica, hitherto only known from the Philippines, the Gulf of Martaban and Cape Comorin, was found in the Zanzibar region, thus extending its known distribution another 2,000 miles round the world. Its range in depth is only 32 metres, although its geographical distribution is so wide.

The one new species described is a Sympagurus, *S. burkenroadi.* The suggestion that the three specimens of Glaucothoe, attributed to *G. hendersoni,* found in the collection may be the larvæ of *S. burkenroadi* is most interesting. Whether the large symmetrical deep-water pagurids known as Glaucothoe are adults or larvæ is now practically settled in favour of the latter view, but it is still a matter of controversy as to whether they are abnormal or normal larval forms—the larvæ of small pagurids which have failed to find a shell and consequently have continued to grow in a larval state, or merely natural larvæ of large forms. The latter solution appears most likely to be the correct one, and Dr. Thompson has brought the matter further by finding these Glaucothoes inhabiting shells, with the abdomen twisted, but still with paired abdominal appendages and a symmetrical tail fan. Thus they are further developed towards adult pagurids than any specimen previously recorded. If they are normal larvæ, they must belong to large adults. In the present case the adult is very probably a Sympagurus, and the characters, except for those which are purely larval, agree very closely with those of *S. burkenroadi.* Moreover, one was found inhabiting the same species of shell. We are certainly well on the way to solving the 'Glaucothoe problem'.

HIGH CRYSTAL HARMONICS FOR OSCILLATOR CONTROL

AN article on this subject by I. E. Fair (*Bell Lab. Rec.*, 21, No. 8; April, 1943) points out that stability is one of the major requirements for oscillators controlling the frequency of radio transmitters. In ultra-high-frequency transmitters it assumes particular importance because a very small percentage change in the frequency of the controlling oscillator may shift the transmitted band many thousands of cycles. At 100 mc., for example, a 0·01 per cent change in frequency means a change of 10 kc., which is as much as the entire width of a broadcast band. Stability in oscillators is secured by some form of tuned circuit. The reactance of such a circuit changes slowly with frequency except over a narrow band in the region of resonance, where a small change in frequency is accompanied by a very large change in reactance, this latter enabling the resonant circuit to act as a frequency stabilizing element. Quartz crystals are eminently suited to control in this way because of their very sharp resonance, which is due to their low values of coupling and dissipation. Their characteristics change only slightly with variations in temperature and voltage, and thus high stability under all conditions is more easily obtained with them than with elements having higher dissipation or greater sensitiveness and voltage.

With the type of crystal most commonly used for oscillators, the frequency of resonance is inversely proportional to the thickness of the crystal. At 10 mc., for example, the thickness of the crystal is only about 6½ thousandths of an inch. Before being used in an oscillator, the crystal must be ground accurately to have parallel faces and to the desired thickness; satisfactory grinding becomes impracticable for crystals appreciably thinner than this. For transmitters requiring higher frequencies it has been almost universal practice to use a crystal with its fundamental resonance below 10 mc. and to employ a harmonic generator to secure the desired high frequency. So far as stability is concerned, this method is satisfactory, but it requires a very appreciable amount of additional apparatus. Not only does the cost of the oscillator go up, but the size also increases, and for many of the high-frequency applications, space is at a premium.

Practically all the circuits used for quartz crystal oscillators require that the reactance of the crystal be positive at the operating point. While harmonics of the fundamental crystal frequency may be used with this type of circuit, therefore, only those giving a positive reactance are possible. Oscillators for a large part of the ultra-high-frequency range have thus been forced to employ harmonic generators, since the 5th harmonic of the thinnest usable crystal is only about 50 mc. This situation has now been changed by a circuit developed in these Laboratories and described in the article, which permits crystal harmonics at least as high as the 23rd to be used for direct control of an oscillator circuit. Oscillators have been built for frequencies as high as 150 mc., using crystals with fundamental frequencies below 10 mc.

SINHALA WEAPONS AND ARMOUR

The *Journal* of the Ceylon Branch of the Royal Asiatic Society for December 1942 contains an article by P. E. P. Deraniyagala on "Sinhala Weapons and Armor". The work of the Sinhalese armourers seems to have elicited great praise from Europeans of the seventeenth century, but one may legitimately doubt whether tempering swords in blood or milk made them any better as weapons, unless it were that they gave greater confidence. The Sinhalese court went in, apparently, for gladiatorial shows; fencing was taught, and foils (or singlesticks) were used in mock combat. The weapons illustrated include the boomerang, both of horn and of wood, and it is worth noting that the Koli name for it is *katariya*: very suggestive of the Latin name for it—*cateia*. The prevalence of the leaf-shaped sword is striking. It is interesting to find in use the feathered javelin, if one can so describe it when the 'feather' was made of metal. Possibly the flat metal vanes were derived from vanes of pandanus leaf such as are used both for crossbow bolts and for javelins in the Assam hills.

A javelin feathered like an arrow appears in the hand of a god or hero in one of Titian's paintings, and Barbosa depicted a similar weapon in the hand of the King of Cochin riding on his elephant; some Eskimo harpoons are so constructed, but the type is a rare one. The author's description of a Sinhalese blowgun is tantalizing. Since he describes it as a wooden tube, it is presumably bored from wood in a single piece. Blowguns of this kind are rarely so long as 80 in. except in Borneo. The tube is tapered, and we are told that "the poisoned dart was fixed with a lump of clay" at the nozzle and propelled by blowing up the tube from the other end, which sounds highly improbable, not to say inefficient. A detailed account of these blowguns, their use and manufacture, of the darts, and of the poison used is much to be desired, as well as some account of the toy blowguns which we are told are still in use. Some of the other descriptions also leave much to be desired. The illustrations are good, but the author is probably wrong in describing Plate I, *b*, as representing wrestlers; the left-hand figure appears to be female and the other to be seated. In general, however, the article contains a useful and well-illustrated account of antiquated Sinhalese weapons. J. H. H.

FORTHCOMING EVENTS

Saturday, September 25

British Psychological Society (at Tavistock House, Tavistock Square, London, W.C.1), at 2.30 p.m.—"Education of the Adolescent".

International Committee for Bird Preservation (British Section and Polish Section) (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 2.30 p.m.—Dr. Jul. Borucki: "The Future of Bird Preservation in Poland"; Mr. Walter E. Higham: "British Featherland" (colour film).

Tuesday, September 28

British Society for International Bibliography (at the Science Museum, Exhibition Road, South Kensington, London, S.W.7), at 4.30 p.m.—Prof. A. F. C. Pollard: "A Proposed Institute of Information".

Sheffield Metallurgical Association and Sheffield Society of Engineers and Metallurgists (at the Royal Victoria Station Hotel, Sheffield), at 6.0 p.m.—Sir Lawrence Bragg, F.R.S.: "The Strength of Metals".

Wednesday, September 29

Manchester Metallurgical Society, The Institute of Metals and The Iron and Steel Institute (at the Engineer's Club Albert Square, Manchester), at 6.30 p.m.—Dr. W. H. Taylor: "Lattice Structures in Relation to Physical Properties of Metals".

Friday, October 1

Association of Applied Biologists (at the Imperial College of Science and Technology, South Kensington, London, S.W.7), at 11 a.m.—Symposium on "The Control of Insects which Attack Stored Foodstuffs".

Saturday, October 2

Association of Scientific Workers (at Essex Hall, Essex Street, Strand, London, W.C.2), at 2.30 p.m.—Conference on "Problems of Freed Europe—The Challenge to the Medical Sciences". Problems of the Occupied Territories: Belgium (Dr. A. Marteau); Czechoslovakia (Dr. V. Kruta); Greece (Dr. A. P. Cawadias); U.S.S.R. (Prof. S. A. Sarkisov); Present Plans for Relief (Prof. J. R. Marrack).

Geologists' Association (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. G. S. Sweeting: "Wealden Iron Ore and the History of its Industry".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Heads of the Departments of Physiology, Medicine, and Surgery—The Bursar, Royal Veterinary College and Hospital, at The University, Reading (October 1).

Educational Psychologist (full-time) to work in the Child Guidance Clinic—The Director of Education, Education Office, Town Hall, Bradford (October 2).

Educational Psychologist (full-time) to be responsible for the direction of the Child Guidance Clinic, and a Psychiatrist (part-time)—The Director of Education, Education Offices, Woodlands Road, Middlesbrough (October 2).

Chair of Naval Architecture—The Acting Secretary of University Court, The University, Glasgow (October 4).

Headmaster of the Montgomeryshire County Junior Technical School, Newtown—The Director of Education, County Offices, Newtown, Montgomeryshire (October 9).

Agricultural Education Officer—The Executive Officer, War Agricultural Executive Committee, County Offices, Aylesbury, Bucks. (October 11).

Director of Robert Gordon's Technical College—The Secretary, Robert Gordon's Technical College, Aberdeen (October 16).

Professor of Engineering—The Registrar, University College, Singleton Park, Swansea (November 20).

Science Master to teach Chemistry and Physics at a leading Boys' School, Jamaica—The British Council, 3 Hanover Street, London, W.1 (endorsed 'Jamaica').

Lecturer in Natural History—The Principal, Saffron Walden Training College, Saffron Walden.

Lecturer in Nature Study and Biology—The Principal, Dudley Training College, Castle View, Dudley.

Dietitian (woman) in the Food Advice Division of the Ministry of Food—The Secretary, Central (Technical and Scientific) Register, Ministry of Labour and National Service, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. ON.F.1425).

Food Analysts for service in the Army Overseas—Ministry of Labour and National Service, Central (Technical and Scientific) Register, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. F.1638).

Director (engineer with considerable experience in workshop operations, teaching and administration preferred) of the Technical School, Addis Ababa, Ethiopia—The British Council, 3 Hanover Street, London, W.1 (endorsed 'Ethiopia').

Assistant Mechanical Engineer for mine on Gold Coast engaged on production of essential war material—The Ministry of Labour and National Service, Central (Technical and Scientific) Register, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.1865X).

CONSUMER NEEDS IN ECONOMIC STABILITY

AN admirable report on "The Transition from War to Peace"* prepared by the Delegation on Economic Depressions, of which Sir Frederick Phillips is chairman, has recently been issued by the League of Nations. Although it has received singularly little notice officially, it provides the essential background in the discussions on employment policy which have been stimulated by the Beveridge Report, the Unilever paper, the Nuffield College statement and other publications on that subject; further, it underlines the recommendations already advanced, that we must think out our policies and measures well in advance, and that we should utilize whatever is possible among the international agencies established to further co-operation during the War. No previous official document has set out so clearly the relations between immediate post-war measures, such as international relief, the removal of industrial controls, rationing and the lowering of taxation, and the larger economic policies for the maintenance of full employment and economic stability.

The report opens with the warning that the War is creating economic changes and upheavals which will intensify greatly the forces leading to instability in the post-war world. Policies must be devised in advance in order that the risks of depression and unemployment may be mitigated, and in particular every effort should be made to think out in advance the methods by which as smooth a transition as possible from war- to peace-economy can be effected. If the economic and social objectives of the United Nations are to be fulfilled, means must be devised for maintaining in time of peace the high levels of production and employment achieved in war-time. Independent action by each country for the achievement of full employment and economic stability would inevitably defeat itself. National policies must be co-ordinated, and this pre-supposes the firm establishment of political security and economic policies no longer conditioned by the fear of war.

To the condition of political security must be added that of popular understanding, and this report makes a notable contribution to the comprehension by the rank and file of the people of how much is at stake. Such understanding is an essential complement to the high degree of statesmanship and courage on the part of those responsible for post-war policy which will be required to resist the spurious 'realism', ignoring the effects of national policies on the interests of other countries, which is already discernible in some of the reconstruction reports which have appeared in Great Britain. We cannot, it is true, foresee the conditions that will obtain at the termination of hostilities, but some of the factors, such as the growth of engineering and machine tool industries in various parts of the world, the acceleration of industrialization in certain agricultural areas, shifts in population, etc., are known; it is the broad lines of policy which, as in domestic reconstruction, demand immediate attention.

* The Transition from War to Peace. Report of the Delegation on Economic Depressions. Part 1. (League of Nations. C.6.N.6. 1943. II. A.) Pp. 118. (London : George Allen and Unwin, Ltd.) 4*s.* 6*d.* net.

Dealing with the objectives of economic policy, the report suggests that first we should think in terms of consumers' needs and then in terms of our mechanical, scientific and human power to satisfy those needs, thus reversing a marked and dangerous tendency of modern publicity policy in industry to which attention was directed by Mr. Alderton Pink in his "Social Reconstruction" and by Mr. Samuel Courtauld in his paper on "Government and Industry". The first objective should be to assure that the fullest possible use is made of the resources of production, human and material, of the skill and enterprise of the individual, and of available scientific discoveries and inventions, so as to attain and maintain in all countries a stable economy and rising standard of living. This was the note struck by Mr. Lyttelton in his speech at Oxford on July 23 when, urging imagination and audacity over the whole field of British industry, he said that it is towards the creation of demand and to the use of inventions that the economic thought of our specialists should be directed.

The second objective should be to ensure that no man or woman able and willing to work should be unable to obtain employment for periods of time longer than is needed to transfer from one occupation to another, or to acquire a new skill. Next, the provision of goods and services to meet the essential physiological needs of all classes of the population in food, clothing, house-room and medical care should be a prime consideration in the use of productive resources. Further, the risk to the individual resulting from interruption or reduction of earning power should be spread over the whole of society; and the liberty of each individual to choose his own occupation should be respected and promoted by equal educational opportunities. Lastly, by courageous international measures of reconstruction and development, the benefits of modern methods of production should be made available to all peoples.

The acceptance of these objectives, which reflect a general orientation of thought that is widely found to-day, should make it easier to avoid or mitigate economic depressions. They involve, moreover, no assumptions regarding the social-economic system or the degree of participation of the State in economic life that may be desired in different countries, other than the responsibility of governments for avoiding large-scale and protracted unemployment.

The second chapter of the report gives an analysis of the domestic issues in the transition from war to peace in countries like Great Britain and the United States, which demonstrates the imperative need for Government preparations in advance and decisions on policy before the War closes. The probable nature of post-war demand is first considered. To get the demobilized men back into employment will be the first concern and may not be too difficult. Production to satisfy consumers' wants, on the other hand, may present enormous difficulties if a runaway price boom and the subsequent collapse are to be averted. The report itself, with its lucid exposition of the reasons why measures taken to control prices and effect an equitable distribution of supplies, both to producer and consumer, should not be abandoned suddenly but relaxed gradually as shortages are overcome, makes an invaluable contribution to the wise publicity required to secure support for such a policy. Government orders and public works are bound to play an important part in facilitating or impeding a smooth transition, and the report repeatedly stresses the necessity for correct timing.

There are two major dangers. First, that projects indispensable for getting the whole national or international economic mechanism functioning again will not be ready, and secondly, that governments will hamper economic recovery by launching too many schemes or launching them at the wrong moment. Governments should endeavour to fill gaps in demand rather than to compete with the market, and the importance of fiscal policies which will encourage enterprise and of government schemes for teaching new skills to meet the new needs that will arise are also stressed. The case for continuance of the controls and for a general government plan over a period of five or ten years could scarcely be better put, and it is all the stronger for the insistence in the report on giving to the consumer all the freedom possible—and freedom from the vice of control for control's sake. No country, however, as the report observes, can hope to keep business active if central control and singleness of purpose are lacking.

No less lucid is the treatment of the international problems of transition in the following chapter. Here again the report insists on the necessity of allowing consumption to expand gradually and smoothly, and that relief and reconstruction should be considered as a single problem. Relief is the first step in reconstruction, and if it fails to reconstruct, it is ineffective charity. It should not only provide for physiological needs, but also enable those requiring help to restore their own economy. Effective programmes of relief and reconstruction will depend on the availability of the essential foodstuffs, raw materials and other goods, and therefore upon the equitable distribution of supplies while supplies are short.

For this reason an international understanding is advocated regarding changes in rations and in the maximum prices to be fixed for goods in the early post-war period. Again, to prevent a scramble for raw products, tonnage, etc., machinery for the purchase and international distribution of such products and for the joint control of tonnage should be continued or instituted, so long as serious shortages persist. As supplies of raw materials become more plentiful, this machinery might be used to stabilize prices by co-ordinating supply and demand and by the creation of buffer stocks. International funds will also be required, for example, in the first instance, to meet the demand for food, raw materials, and certain finished goods, to feed and clothe the populations and gradually to restart production in the stricken areas, as well as for capital to repair the physical damage and make good the wear and tear suffered during the War. The availability of such funds will depend on the relaxation of exchange controls and the possibilities of effecting multilateral clearing and conducting multilateral trade.

In this connexion the report refers to the proposals of the British Treasury and those of the United States to establish some form of international clearing or equalization fund. The control of inflation, the principles on which long-term lending should be based, and the dangers which may be encountered in an effort to realize the general objectives of commercial policy already laid down in the Atlantic Charter and in Article VII of the Mutual Aid agreements, are also discussed and analysed. In conclusion, the report emphasizes the necessity of finding means of co-ordinating the policies of the various international organs required, and, secondly, that economic policy must be correlated with political.

The great value of the report is first in its clear statement of the long-term objectives on which it is based, and it is encouraging to find that those objectives are already accepted in many quarters in Great Britain—for example, in the report on reconstruction issued last year by the Federation of British Industries. In contrast to the timidity of the Federation's report, however, the present report is based on a belief that courage and enterprise on the part of governments and individuals in making prompt adjustments to changing requirements can secure a prosperous equilibrium. That belief also inspires the Planning broadsheet "Employment for All", the Unilever paper on unemployment, and the Nuffield College statement on "Employment Policy and the Organization of Industry after the War".*

The PEP broadsheet in question emphasizes the importance of agreement between the leading nations on economic policy and the special responsibility of the United States and Britain to put their house in order. If they establish full employment and a high demand for imports, they will go a long way towards increasing prosperity in the world as a whole. The transition from war to peace is seen, as in the League of Nations report, as a gradual process, and the broadsheet attempts, first, to outline the guiding principles of a policy for full employment, and secondly, to indicate the operation of those principles in the post-war years.

The immediate cause of cyclical and long-term employment is due, according to the PEP broadsheet, to a decline in demand for capital goods, due in turn to a low demand for consumption goods. Under-investment is largely the result of under-consumption, and the first attack on unemployment is a policy to increase consumption. In this attack the social security system outlined in the Beveridge Report is an important factor, and redistribution of income from higher to lower income groups is also advocated as a means of increasing the spending of the community as a whole.

The second line of attack is investment policy, and here the broadsheet advocates the use of public works as a powerful instrument of business stabilization. The extension of the sphere of public investment is also recommended, and such investment would be determined not by ordinary commercial profit but by social requirements and by social standards such as nutrition, housing and clothing, which could be scientifically ascertained. It is urged that by limiting the sphere of private investment and controlling much of the remainder, the impact on general economic activity of the fluctuations in private investment, which are the main cause of cyclical fluctuations, would be reduced. It is believed that the raising of consumption through progressive redistribution of income and the stabilization of a large part of investment activity would in themselves have a sufficient stabilizing influence on the remaining sphere of private investment.

The proposals of the Nuffield College statement are somewhat different. It recognizes the excellent results to be looked for from a system of social security, and that measures to stimulate investment are indispensable to secure full employment. While, however, it holds that public works, including works undertaken directly at the orders of public bodies and works undertaken by private agencies or contractors as a result of public encouragement, constitute a valuable means of maintaining the level of investment, the cost of such investment should not be met out of higher taxation, as this will react adversely on consuming power. In times of economic difficulty the burden of taxation should be lowered rather than increased.

To enable the State to plan and stimulate investment over a system of priorities according to social needs, it advocates a general extension of long-term economic planning and an extension of the public corporation principle to cover a number of industries and services which are among the largest consumers of capital goods, especially the essential transport services and the main public utilities, both for extensions and replacements. Building, in particular, is a key industry in this connexion, and State policy should be directed towards securing a high and increasing level of output during the period immediately after the War, and thereafter towards ensuring a reasonable degree of stability, in terms of a long-period programme of building, to be accelerated or retarded as part of the deliberate policy of maintaining the level of real investment.

For the execution of this policy, the statement makes one proposal which has already been encountered in the Unilever paper. First, a new method of presenting the national accounts, in which capital expenditure, which would not require to be covered by taxation, is presented to Parliament in a capital budget, embodying plans of economic development framed to ensure a progressive rise in standards of living and amenity. Such a policy of a national stock-taking, which involves the creation of a more efficient and better co-ordinated statistical service than Great Britain has hitherto possessed and the establishment of a permanent Control Statistical Office, adequately staffed for prompt service, is an integral part of this proposal. Secondly, it suggests the establishment of a National Development Board to which should be entrusted the control of funds available for public investment, as well as the functions now performed by the National Debt Commissioners, the work relating to local loans, the functions of the Public Works Loans Board, and the supervision of all State investments in productive enterprise, together with the licensing of capital issues or other forms of capital expenditure which might be made subject to public control. The Development Board, as well as economic planning generally, including the location of industry, would come under a new Minister for National Development.

---

* Employment Policy and Organization of Industry after the War: A Statement. Nuffield College. (London: Oxford University Press, 1943.) 2s. net.

The Unilever paper, it will be recalled, considers that a general planning board would be almost helpless in regard to fostering progress and would be apt to discourage rather than stimulate ventures. Again, in contrast to the PEP broadsheet, the Unilever paper holds that under-consumption is in reality a consequence of the interruption of productive activity caused by the trade-cycle and therefore a symptom rather than a cause of depression. Social insurance schemes can make an important contribution to the solution of the problem of poverty, but the real cause of unemployment is irregularity of capital investment, and the essential measures required are government measures which should be planned well in advance and ready for immediate application. Industrial and international measures are indeed also required, and the close similarity between those detailed in the Unilever paper and those in the League of Nations report is encouraging evidence that there is some consensus of opinion as to the measures to be taken.

No one reading the three British contributions on this subject of full employment can doubt that support will be forthcoming in Great Britain for bold planning, or that its industrial leaders will be lacking in initiative and enterprise, or fail to show the flexibility and efficiency required. Even where there are differences of opinion as to primary causes, the action recommended is essentially similar, differing slightly in the relative emphasis on particular points. The importance of correct timing is already appreciated, and in every statement or report we find condemnation of the delay in implementing the proposals of the Barlow Report and in finding a solution of the problems of compensation and betterment studied by the Uthwatt Committee.

On the need for Government decision on policy and for executive action, these reports and papers, like many others, leave no room for doubt. In building and physical reconstruction, in town and country planning, in agriculture, in matters of compensation and betterment, of local government and regionalism, there are confusion and a growing sense of frustration due to the Government's failure to take decisions and announce its policy. Ministerial distinctions between delay and consumption of time increase the scepticism and cynicism which are a disheartening accompaniment of our progress in the War. They are unworthy of the leadership which has brought this nation through the dark days of 1940 and inspired the strenuous exertions, sacrifices and achievements which are bringing us within sight of our goal. No demands made on the Government for the conduct of the War can alter the fact that primarily on them does it depend whether we are to become masters rather than servants of the forces that make for change, and whether we succeed in "the great tasks of rebuilding, of securing the advance of ideas and not letting it be swept back by mere tides of lassitude, exhaustion or reaction—the reconstruction and consolidation of our country in the gains which we shall have made during this hard and long trial". Thus spoke the Prime Minister, and his words must be matched quickly by decision or delegation.

THE ADVANCE OF BIOCHEMISTRY

Advances in Enzymology and Related Subjects

Edited by F. F. Nord and C. H. Werkman.
Vol. 1. Pp. x+433. (New York: Interscience Publishers, Inc.; London: H. K. Lewis and Co. Ltd., 1941.) 5.50 dollars; 33*s*. net.
Vol. 2. Pp. viii+374. (New York: Interscience Publishers, Inc.; London: Imperia Book Co. Ltd., 1942.) 5.50 dollars.
Vol. 3. Pp. viii+408. (New York: Interscience Publishers, Inc., 1943.) 5.50 dollars.

"ADVANCES in Enzymology" is the successor of "Ergebnisse der Enzymforschung", which appeared first in 1932 and ceased to exist after its eighth annual publication in 1939. During this period the "Ergebnisse" achieved a high reputation for the authoritativeness of its articles, which covered most fields of biological chemistry. It was consulted by research workers, teachers and students, who found it a ready means of keeping abreast of a complicated and diffuse literature. Its complete disappearance would have meant a great loss. Fortunately, it has been born again under the title "Advances in Enzymology": edited by Nord and Werkman, and published in the United States. The first three volumes of this annual publication have now appeared and cover the years 1941–43. The high scientific quality of the articles that was associated with the "Ergebnisse" is maintained, and although there has been obvious restriction in choice of authors (due to war conditions), the matter published is instructive, critically written, and embodies many of the most recent developments in biochemistry.

No major advance in the study of enzymes or in our knowledge of the working of the living cell can be imagined taking place without due regard being paid to the composition of proteins, which are known to form the basic structure of enzymes. "Advances in Enzymology" commences appropriately, therefore, with an article (vol. 1) on protein structure by Bull. He deals in an interesting and stimulating manner with the work of Bergmann, Astbury, and Wrinch, regards with extreme conservatism the classification of proteins on a basis of molecular weights, and discusses critically the Bergmann theory that all proteins are made up of whole-number multiples of a definite number of residues. Astbury, whose X-ray analyses of proteins have done so much to advance our knowledge of their structures, has in a later article (vol. 3) considered the propositions of Bergmann and Niemann that (1) the numbers of the different kinds of residues, and also the total number of residues, in the molecule, are always of the form $2^n 3^m$ where n and m

are positive integers or zero; and (2) the residues of any one kind occur at a regular periodic interval along the polypeptide chain. He shows that the best evidence for the validity of the $2^n 3^m$ rule comes from the analytical work of Chibnall on the composition of edestin, though the latter's results with egg albumin do not support the rule so clearly. He concludes from a variety of evidence that the rule operates in the building of the constituent parts of proteins, and sometimes in the building of the whole protein molecules. Astbury reviews the chemical and X-ray evidence bearing on the structure of fibrous proteins (silk fibroin and the keratin-myosin group) and of a number of other proteins, and proposes a model based on the principle that, in general, polar or non-polar side-chains occur alternately along the polypeptide chain.

The fact that plant viruses are nucleoproteins capable of self-multiplication throws into prominence the fact that chromosomes are largely composed of nucleoprotein, and suggests the possibility that the nucleoprotein of chromosomes may also be capable of self-multiplication. Mirsky (vol. 3) ably presents the beginnings that have been made in biochemical investigation of chromosomes and of nucleoproteins generally. He discusses the nucleoproteins of nucleus and cytoplasm, and their relationships to virus proteins. Those of the latter which have been isolated are ribose nucleoproteins—differing thus from the desoxyribose nucleoproteins of the cell nucleus—and are more comparable with the self-duplicating plastids, the chloroplasts, in the cytoplasm of many plants. The great accumulation of desoxyribose nucleoprotein in the chromosome suggests that these proteins are identical with the genes, or are intimately related to the genes. Mirsky refers to the view of Caspersson that the presence of high concentrations of ribose nucleic acid in the cytoplasm during growth is in some way concerned with protein synthesis.

It is obvious that the bearing of nucleoproteins on catalytic processes in the living cell is of the greatest importance for our understanding of cell mechanisms. This is further emphasized in the recent findings concerning the mechanism of enzyme action.

It is now known that many oxidizing systems in the cell require the participation of special proteins and also of defined chemical groupings (sometimes called prosthetic groups, sometimes co-enzymes). The complex of protein and grouping forms an enzyme system. Cozymase—one of the best known of these groupings—is a nicotinamide-adenine-dinucleotide; it can combine with various specific proteins to produce a variety of enzyme systems, each having separate and specific catalytic powers in the oxidation of substances important in cell metabolism. Flavin-adenine-dinucleotide is another such grouping having associations with specific proteins concerned with oxidative processes. Such matters as these are discussed by Green (vol. 1), who deals with the influence of so-called 'trace' substances on enzyme activity. He refers also to the co-enzymic roles of diphosphothiamine, copper, and zinc, and to the possibility that many substances of high physiological activity (insulin, thyroxin, and other hormones) may play a part in the body similar to that of the coenzymes.

The specificity of action of an enzyme system depends not only upon the chemical nature of the co-enzyme but also upon the constitution of its specific protein. There are large groups of enzymes, however (for example, the lipases, sulphatases and proteinases) which are not known to be associated with co-enzymes; their properties must be deemed at present to be determined solely by the configuration of groupings embodied in the proteins themselves.

The general problems of the classification and the specificity of action of proteolytic enzymes are dealt with by Bergmann (vol. 2), and by Bergmann and Fruton (vol. 1), while peptidases receive attention from Johnson and Berger (vol. 2). Bergmann clarifies the somewhat complicated picture which has arisen concerning the specificities of action of the whole class of proteinases and peptidases. He points out that these enzymes may act in two different ways. One type of reaction results by the specific action of a single enzyme on a single peptide bond, while the other type consists of a sequence of coupled reactions involving several peptide bonds and several enzymes. It is the latter type which must be dominant in protein synthesis—if indeed the thesis is correct that protein building in the cell is the result of proteolytic enzyme activity. Johnson and Berger review critically our present meagre knowledge of peptidase systems and point out that "too few current papers take sufficient cognisance of our complete ignorance of the enzymatic constitution of most peptidase systems".

Descriptions of the chemical nature and modes of action of certain enzymes important in oxidative processes in the cell, namely, catalase, diamino oxidase, and verdoperoxidase, are given by Sumner (vol. 1), Zeller (vol. 2), and Agner (vol. 3), respectively.

The oxidative enzyme systems playing a part in tea fermentation form the subject of an interesting article by Houghton-Roberts (vol. 2). He shows that the chemical changes taking place after the rolling of tea leaf—when something like 95 per cent of the tannins present become oxidized—can be explained on the basis that mechanical damage interferes with the normal oxido-reduction equilibrium between the *o*-quinones, produced by tannin oxidation, and carbohydrates in the leaf. As a result of this interference, which leads possibly to dilution of the co-enzymes involved, the *o*-quinones are rapidly condensed to complex tannins.

Enzyme systems in the plant, especially those leading to sucrose formation, are dealt with by Kurssanov (vol. 1), while enzyme systems in tumours form the subject of an article by Greenstein (vol. 3). Greenstein concludes that no simple generalization will cover enzymic behaviour of all groups, or even of any one group, of tumours. The direction and magnitude of the changes taking place when a neoplasm develops depend on the species of animal and the strain in any given species, as well as on the kind of tumour. A clear picture of what takes place can only be obtained by systematic investigation of the many enzyme systems present.

The study of the effects of temperature on enzyme kinetics is reviewed by Sizer (vol. 3). Van Slyke (vol. 2) describes methods in vogue for the study of the kinetics of hydrolytic enzymes such as urease and arginase, and gives a quantitative formulation of the kinetics of the two-phase reaction.

Turning from the study of enzymes to consideration of metabolic systems, excellent articles are to be found on the subjects of photosynthesis (Van Niel, vol. 1; and Frank and Gaffron, vol. 1); of the breakdown of cellulose by micro-organisms (Norman and Fuller, vol. 2); and of the role of micro-organisms in wine-making (Cruess, vol. 3). Van Niel deals only with the phenomena of bacterial photosynthesis. He describes (together with other matters) the metabolism of the green and purple bacteria, and interprets the events taking place on the basis of a photosynthetic carbon dioxide reduction depending on the simultaneous oxidation of special hydrogen donators. The facts and interpretations of photosynthesis in both plants and bacteria are fully considered by Frank and Gaffron, who deal with the thesis that the anaerobic type of photosynthesis is the same in *all* cells, but is supplemented in green plants by the capacity of liberating gaseous oxygen.

Norman and Fuller's article on cellulose decomposition is of particular value just now when knowledge is wanted of the details of the breakdown of straw and plant residues in composts, in soil, and in the animal digestive system. These authors show that important aspects of the breakdown of cellulose can only be investigated by the use of mixed as well as of pure cultures of organisms.

Advances in knowledge of carbohydrate metabolism are reviewed by Barron (vol. 3) and by Krebs (vol. 3). Krebs considers in detail the oxidative changes undergone by substances concerned in carbohydrate breakdown in the living cell. He examines the various schemes and cycles of operations in which these substances may be involved. Barron's article deals mostly with the steps involved in carbohydrate fermentations. It indicates the vital importance of phosphorylations and of the key position taken by pyruvic acid, "the hub towards which comes fermentation, from whence starts oxidation". The importance of the phosphate bond in the changes occurring in the living cell receives due recognition in an interesting article by Lipmann (vol. 1), who describes, in the light of his concept of the energy-rich phosphate bond, many of the metabolic reactions involving phosphorylation and phosphate transfer.

One of the most important advances made recently is the demonstration by Wood and Werkman of the heterotrophic assimilation of carbon dioxide. These authors describe (vol. 2) the phenomenon in detail, and also describe the parts played by carbon dioxide in the metabolism of bacteria and animal tissues.

Advances in biochemistry necessarily involve increased knowledge of the constitution and properties of vitamins and hormones. Biotin receives attention from Hofmann (vol. 3); the elucidation of its structure by du Vigneaud and his colleagues is described, as are its occurrences in free and bound forms, and its role in animal nutrition. Biotin is a most potent growth factor; it is now receiving attention as a possible factor in the development of tumours. Another important growth factor is pantothenic acid, the structure and properties of which are described in vol. 3 by R. J. Williams, who has done so much to elucidate the properties of this vitamin. Deficiency of pantothenic acid in the diet leads to diverse pathological changes, among which are dermatitis and a depigmentation of hair. In fact, pantothenic acid is receiving increasing attention as an anti-grey hair factor. The chemistry and physiology of vitamin K—a 2-methyl-1 : 4-naphthoquinone derivative which is connected in some manner with enzymes involved in blood coagulation, and is sometimes referred to as an antihæmorrhagic factor—are described by Dam (vol. 2). The important adrenal cortical hormones (corticosterone, dehydrocorticosterone, and androsterone) are dealt with by Pfiffner (vol. 2).

Other articles on the structure of glycogen, the respiration of Aspergillus, digestion in the lower vertebrates, and on some properties of bacteriophage, complete a valuable series of reviews, to the continuance of which all biochemists will look forward with interest.

J. H. QUASTEL.

SOIL AND PLANT ANALYSIS

Soil and Plant Analysis

A Laboratory Manual of Methods for the Examination of Soils and the Determination of the Inorganic Constituents of Plants. By Dr. C. S. Piper. (A Monograph from the Waite Agricultural Research Institute.) Pp. xiv+368. (Adelaide: University of Adelaide, 1942.) *15s.*

BOOKS on methods of analysis can be divided into two classes, one of which is the 'collected methods' type. Here each chapter or section of the book is devoted to a specific analysis or group of related analyses, and gives the working details of all or nearly all the existing methods. Such books are not only very useful and convenient but also are a necessity for those analysts to whom the original papers in the literature are not easily accessible. It is, however, the other class of book that the analyst most appreciates, namely, the book in which he is not bewildered by an array of methods but is presented with a selection recommended from considerable experience. Dr. Piper has compiled his book along these lines, and all the methods, with a very few exceptions, are those in use at the Waite Agricultural Research Institute. Concise, and more important still, precise working details are given with ample explanation and a wealth of guidance and help.

In the first section of the book, dealing with soils, the methods, both physical and chemical, are those that are useful in soil survey work and in the study of long-term factors affecting soil fertility. The very simple and rapid methods for estimating fertilizer requirements of soils have not been included, since none has been generally acceptable; and in the opinion of the author such tests are unlikely to simulate the conditions in the soil during the growth of the plant. In the second section of the book, Dr. Piper presents methods for the determination of the inorganic constituents of plants which form a logical alternative to rapid soil methods and are a more reliable approach to the availability of soil minerals, especially those supplying trace elements. Plant analysis is of supreme importance in fertilizer investigations and in studies of animal nutrition problems.

Full treatment is given to the subjects of hydrogen-ion concentration, mechanical analysis, single-value soil constants and exchangeable ions. The methods for the determination of the sesqui-oxides, alkaline earths and alkalis contain just those essential details without which the analyst may find himself in difficulties. The chapter on wet- and dry-ashing is a valuable contribution. To those concerned with plant analysis and to many others the determination of the trace elements will perhaps appeal most of all. Here an organic reagent, dithizone, plays the leading part in the scheme of inorganic analysis. It is used with much success in separating most of the inorganic elements.

There can be no doubt that this book is an outstanding addition to those already written on this subject.

A Family of Devon

Their Homes, Travels and Occupations. By Dr. Vaughan Cornish. Pp. viii+56+10 plates. (St. Leonards-on-Sea: King Bros. and Potts, Ltd., 1942.) 10*s.* 6*d.*

DR. VAUGHAN CORNISH is a geographer who, in addition to his scientific studies of waves on sea and land and kindred geophysical phenomena, has devoted particular attention to the æsthetic aspects of natural scenery. He has long taken an active part in preserving the amenities of rural England and is the donor of South Combe Farm on Sidmouth Cliffs as an open space in perpetuity.

At the beginning of last century, George Cornish, who had been an officer in the Royal Marines and served in India as an A.D.C. to Sir John Shore, purchased an estate at Salcombe Regis, now included in the Sidmouth Urban District, and there founded the Sidmouth branch of the family. Dr. Vaughan Cornish is one of his descendants, and in this book he traces associations of members of the whole ancestral group with the part of South Devon in which they had their homesteads. The book is, however, more than a genealogical record and presents a picture of the life of lesser country gentry farming their own lands from Tudor times to the present day.

Throughout this period the intellectual interests of one or another of the family have been influences for good in the history of England. So long ago as 1775, some letters from Dr. James Cornish, "On the Torpidity of Swallows and Martins", were published in the *Philosophical Transactions*. He was the first of the family to branch out into authorship, and a number of other members have worthily followed him in literary, artistic and scientific fields. On the natural history and country-life sides, C. J. Cornish, a master at St. Paul's School, was a brilliant writer on these subjects in the *Spectator* and other journals. He was a brother of Dr. Vaughan Cornish, whose wide outlook and acute vision have maintained the cultural tradition of the family which he represents so well.

Practical Emulsions

A Handbook of Emulsions, Emulsifiers and Methods of Formulating and Making Emulsions of Practical Value in Industry. By H. Bennett. Pp. x+462. (Brooklyn, N.Y.: The Chemical Publishing Co., Inc., 1943.) 5 dollars.

THE principal object of this book is to deal, in reasonably small compass, with emulsions for the practical worker. Concentrating upon the art of making and applying emulsions, it touches only lightly upon the theoretical aspects, and illustrates these main themes by reference to practical usage.

Rather more than half the book is devoted to emulsion formulæ and directions for formulation. The remainder, under the term "General", outlines such topics as emulsifying agents, types of emulsions and assessment of stability, general methods of preparation and types of equipment employed, together with the related topics of foams, dispersing and wetting agents, and demulsifying and defoaming agents. While much useful practical information is to be found in this part, it does give the very definite impression that emulsion practice is still carried on as an empirical art with very little guidance from an understanding of the basic factors involved. Since the theoretical aspects are touched upon, albeit only lightly, a brief but lucid exposition of modern advances would have been beneficial in enabling the practical worker to appreciate some of these more fundamental factors. In this connexion one is surprised to see the orientated wedge theory of emulsification given so much prominence. It is felt that this part could with advantage have been considerably reduced, leaving all theory to specialized treatises on the subject.

The second part, under the heading of "Formulas", gives an excellent idea of the multitudinous applications for emulsions: agricultural sprays, cutting oils, cosmetics, foods, lacquers, lubricants, paints, paper, waterproofing and so on. No less varied are the ingredients used. The emulsion technologist should find these recipes very useful.

The book is well printed and typographical mistakes are few.

A. E. ALEXANDER.

War-Time Food for Mother and Child

By Dr. Geoffrey Bourne. Pp. 78. (London, New York and Toronto: Oxford University Press, 1942.) 2*s.* 6*d.* net.

THE Minister of Food has shown his appreciation of the special needs of pregnant and nursing women and of growing children by the special allowances that he has made for these groups. However, these requirements are not so well realized by the general public. Anything that hammers in the fact that pregnant and nursing women and young children are the most vulnerable of our citizens is welcome. Dr. Bourne's book gives a clear explanation of the requirements of pregnancy; this is enlivened by information about the development of the fœtus not commonly found in books on nutrition. He might, perhaps, have brought out more clearly the fact, obvious but often overlooked, that the nursing woman has to supply all the constituents of her milk either from her food or from her own body. The extra needs during lactation are therefore more unquestionable than during pregnancy.

Dr. Bourne gives detailed advice about diets, suited to present conditions, from early pregnancy to school years. In some respects this is less satisfactory than the account of requirements and may be unrealistic. For example, as breakfast for a pregnant woman: "In place of orange or lemon juice eat black and red currants or drink infusions of hip and haws when they are available . . . . The water left, when boiling vegetables . . . can be flavoured with Marmite or meat extract and then make a pleasant drink. . . . After the vitamin C supplement a herring or kipper, if obtainable, may be eaten instead of an egg. . . ." How many people could get currants, during their short season, in the past two years? Why not tomatoes, which have a longer season and have been distributed widely if erratically? What proportion of breakfasts can supply egg or fish? The vegetable water would be kept from the previous day; how much ascorbic acid would it contain unless kept in a refrigerator? Such advice tends to undo the good done by the valuable exposition of special requirements. In the more general discussion of diet, Dr. Bourne does not bring out the special importance of green vegetables—the food of which we can get more than we could in peace-time.

With these criticisms the book can be recommended for the material that is not found in other books on nutrition.

SCIENCE IN WESTERN SZECHUAN

II. BIOLOGICAL AND SOCIAL SCIENCES

By Dr. JOSEPH NEEDHAM, F.R.S.

British Scientific Mission in China

IN the preceding article* something has been said of the state of physics and chemistry in the five universities at the great city of west Szechuan, Chengtu. On the whole, the biological work there is even more active. On the West China Union (Huahsi) University campus some excellent taxonomic and ecological work is being done. Thus Dr. Chang Ming-Chun of Huahsi specializes on gastropod systematics and embryology, while Dr. Liu Cheng-Chao of Yenching is a really outstanding authority on Asiatic Amphibia. His collections and data are astonishing, including torrent adaptations, strange breeding habits, etc., and many new species, such as *Vibrissaphora boringii*, a whiskered frog. There are great opportunities for experimental embryology here, which have so far not been taken advantage of. Dr. Liu himself goes on collecting expeditions in the Tibetan borderlands which involve real hardship and danger. For comparative physiology also there are great opportunities, for example, to work with the giant earthworms of the Mount Omei region, species of Pheretima, commonly up to 3 ft. long and at least 1 in. in diameter.

Parasitology has an eminent representative in Dr. Chang Kuei of Chilu, who has done remarkable work on a hookworm survey of the province, with the help of the Rockefeller Foundation. Infestation has a very close association with the maize and sweet potato pattern of cultivation rather than with the rice pattern. If pronounced, it leads to strange phenomena such as geophagia. Among the activities in the fine biological building on the Huahsi campus are also a service for the preparation of biological models in painted plaster for schools and universities, and of injected biological specimens. There is also an interesting project in domestic science under Dr. Peng Yuing-Hua, popularizing jam-making among the Chinese people in order to avoid the hitherto normal annual wastage of fruit. There is a strong school of plant pathology, economic insect pest survey, etc., under the direction of her husband, Dr. Ho Wen-Chun. They both studied in Iowa. Last, but not least, Dr. F. Dickinson's work on animal breeding, fruit-tree improvement, etc., has benefited the whole province and is known throughout China.

Plant pathology leads to reference to a sixth university not mentioned in the preceding article, namely, the provincial University of Szechuan, occupying its own new buildings on an unfinished campus some distance away from Huahsi University. Its strongest side is agricultural science, so that when the Szechuan Provincial Agricultural Experiment Station is also taken into account, the importance of Chengtu as an agricultural centre can be well seen. The plant pathologist at the Experiment Station is Dr. Ling Li, who has described mosaic disease in Cruciferæ, and has published many papers in such journals as *Phytopathology*. He recently collaborated with the Imperial mycologist from New Delhi, Dr. Watts Padwick, who visited China as a technical expert at the invitation of the Chinese Government. The authority on insect pests at Szechuan University is Dr. Tseng Shen, who is very active against tobacco diseases; he leads expeditions through the countryside, giving instruction to the peasants. The Agricultural Experiment Station actually operates an insecticide factory of considerable size, producing pyrethrum powder, copper carbonate and arsenate, etc., with very primitive but serviceable apparatus. In Dr. Liu Chwing-O, the University of Szechuan has an exceptionally eminent authority on wood-boring insects, especially the larvæ of longicorn beetles; she is in touch with the British Museum (Natural History) through the British Scientific Mission. Her work on coleopteran parasites of coleopteran wood-borers is of much interest.

Other departments, too, are worth a visit. At Szechuan Agricultural Experiment Station there is good work going on in crop improvement under the active Dr. Li Hsien-Wen, an associate of the well-known geneticist Dr. Beadle. Dr. Li produces new disease-resistant wheats for the Chengtu plain, but is also interested in cytoplasmic inheritance of variegation in Triticum, and the production of new species of Setaria by crossing. Dr. Li points out that a certain kind of barley, selected at the University of Nanking in 1937, was taken to the United States by Dr. Love, and proved to be so good that 'Wang barley' has by now far more than paid for all the expenses incurred by the United States in sending technical experts to China. Then at the University of Szechuan the botanical department is outstanding. Under Prof. Fang Wen-Pei, very extensive collections of west Chinese and central Asiatic plants have been made; and duplicates are available for exchange with Western collections. Prof. Fang has recently produced a most beautifully illustrated work "Icones Plantarum Omeiensis", which includes descriptions and pictures of new genera as well as many new species. Copies have been sent to Kew and other centres.

In sericulture (Prof. Wang Tao-Yung) the University of Szechuan is strong too; work is under way on comparative silk-gland histology, bacterial diseases of silkworms, survey of mulberry varieties, and physiology of the wild race. Thirty-eight pure lines and many hybrids are maintained in this laboratory. Here again, after the War, there would be great opportunities for a physico-chemical attack on the nature of the spinning process, that is, how the liquid gland contents become the spun fibre. The stranger is surprised to be told that from each cocoon 500 m. of silk fibre can be drawn. Since the old form of the Chinese character for Szechuan contains the radical for insect, Szechuanese sericulturists believe that sericulture originated in their province.

In horticulture also the Szechuanese have an ancient tradition, for this province is thought to have been the original home of the orange. The department at the University of Szechuan points with pride to the treatise of the Yuen dynasty (about A.D. 1200) by Han Yuen-Chih called the "Orange Record". Chinese horticulturists are looking to Britain's Food Investigation Board to give them advice about the erection of refrigeration plants in the province after the War; let us hope that Britain will not be too behindhand in responding to the need for technical experts in China. One worker here comes, indeed, from East Malling, Dr. Chang Wen-Tsai. In the Forestry Department, there is little available knowledge about tung oil trees, for example, not possessed by Dr. Li Ying-Chen. Lastly, in agronomy, Dr. Yang Yin-Kuei is working on colchicine polyploidy, and trying to get the farmers to plant maize as an emergency crop, if the rice fails in July, so that they may have it in September.

---

* See NATURE, September 25, p. 343.

In medicine and dentistry, Chengtu is as important as it is in agriculture. The medical school of the Huahsi University hospital under Dr. Leslie Kilborn was famous throughout China long before the War, and though it has lost in access to new equipment since, it has gained by the influx of personnel from the evacuated medical schools. Thus in the Department of Pathology there is the eminent Dr. Hou Bao-Chang of Chilu, now interested mainly in medical geography, and ably assisted by Dr. Chiang Ching-Fen, the daughter of Peter Chiang, the first Chinese to study biochemistry at Cambridge. The difficulties of work in China may be illustrated by the fact that all the records of this group were lost by bombing, started again and lost again by fire; work on leprosy had to be stopped for lack of funds, an experimental monkey colony was started, but had to be abandoned owing to financial straits, and all the time they had to make even their own typewriter ink, which faded on the records, and their own Canada balsam from local resins, which often spoiled the specimens. Perseverance is an inadequate word unless we add some adjective such as heroic.

So also in the Physiology and Pharmacology Departments; Dr. Feng Ta-Rjan of Huahsi investigates Chinese drugs such as the anti-dysmenorrhea *tang-kuei* and the uterine stimulant *i-mu-tsao*, while Dr. Chu Rjen-Bao, an incomer from Nanking (and former collaborator of Dr. A. S. Parkes), works on the sex hormones in relation to the pituitary and spermatogenesis. The Dental College, under Dr. Lindsay and Dr. Agnew, was always pre-eminent throughout China, and with such colleagues as the odontal morphologist Dr. Chou Shao-Wo, bears the greatest part of producing first-class modern Chinese dentists. This work is so necessary for the people of China that it ought to be expanded enormously, and deserves the fullest official financial support.

The Huahsi Medical School is not, however, the only one in Chengtu. There is also the Chungyang Medical School, belonging to the National Central University at Sandy Hook, already described in the third of this series of articles. Here also the standard is very high, particularly in the Departments of Physiology (under Dr. Tsai Chiao, now absent in the United States on a lecture tour), Biochemistry (under Dr. Cheng Li-Bin) and Anatomy (under Dr. Pan Ming-Tse). In Dr. Tsai's absence, Dr. Hsu Feng-Yen (a former collaborator of Prof. Lovatt Evans) presides over no fewer than fifteen research workers, including an able young woman from Amoy, Miss Chu Chiung-Yuing, who is studying acetylcholine physiology. Other work concerns a non-histamine smooth-muscle stimulant found in blood, the intestino-intestinal reflex, the anti-hæmolytic action of cholesterol, and a little-understood local disease known as Chiating paralysis and believed to be due to barium poisoning following the use of insufficiently purified salt. Dr. Hsu and Dr. Cheng pointed out to the visitor with justifiable pride perfusion pumps and kymographs all made in the workshops of the medical school itself. As for the Anatomical Department, Dr. Pan and his colleagues pursue a rather original line of study, namely, the physical anthropology of the soft parts, on which Dr. Pan has himself published many papers. Dr. Pan thus combines the interests of his master, the late Sir G. Elliot Smith.

In this connexion, it should be noted that social anthropology is also not lacking at Chengtu. The distinguished anthropologist Dr. Li An-Che (a pupil of Prof. Sapir) heads the Huahsi Institute of Sino-Tibetan anthropology, which deserves much more support than it has so far, in war-time, been able to receive. Mrs. Li An-Che (Yu Sse-Yü), sister of Yu Dao-Chuan, the Tibetan scholar now in England, also works in the field and speaks Tibetan.

Coming now to Chiating, the biological laboratories of Wuhan University are housed, not in the city, but some distance outside it; they include an old stone thick-walled watch-tower which makes an excellent laboratory. It was Dr. T'ang Pei-Sung (now of Kunming) who deserves a great deal of credit for building up biology at Wuhan. To-day Dr. Gao Shang-Yin, who was trained at Yale, with his collaborators, have there the only laboratory in Free China devoted to non-medical bacteriology; while below the ingenious Dr. Shih Shen-Han teaches plant physiology and pathology, and in the watch-tower above Ling Chun-Yo devises new electrodes for blood *p*H and investigates the permeability of erythrocytes. The watch-tower contains one of the few Warburg manometer sets in China. With its lovely view over the river, the watch-tower symbolically reminds one of John Donne's

> "But up into the watch-tower get . . ."

though the moral is very different. A pool in the river below the laboratories is no ordinary river pool, for there each year a population of freshwater medusæ develops (2,000 miles from the sea). This medusa has been named *Craspedacusta kiatingi* by Dr. Gao and Kung Li-Hua, who have also made studies of its physiology. The whole group of biological departments is headed by Dr. Chang Ting, a botanist of considerable seniority.

Not far from the city is to be found, on a high eminence beneath a tall pagoda, the National Forest Products Research Station. Under the energetic direction of Dr. T'ang Yao, who until the War was in close contact with forestry in most other countries, this is an active centre. While the United States, for example, has only about a thousand species of forest-trees, China has two thousand; in each case about 10 per cent are really valuable. The Station possesses a fine collection of timber specimens from all over the world as well as China, and an admirable reprint and microfilm collection.

Proceeding down the Yangtze, our next biological port of call would be Tongchi University at Appletree Rapids. Here the biological departments are also extremely good. In physiology there is Dr. H. Stübel, who has worked in China for more than twenty years, and with Dr. Liang Tze-Yen was responsible for some historical work on the fine structure of muscle fibres. In botany there is Dr. Wu Yin-Chan, and in zoology Dr. Tung Ti-Chao, who is undoubtedly the most active experimental embryologist in China to-day. He collaborates with his wife, Dr. Yeh Yu-Fung, and they contrive to produce really excellent work in cramped and very uncomfortable surroundings. This has been done, not only by improvising at all stages, but also because Dr. Tung (a pupil of Prof. A. M. Dalcq at Brussels) chose an important problem which could be worked on with the minimum use of stains, wax, microtomes, etc. This problem is that of the determination of ciliary polarity in the embryo, which the Tungs link up with the determination of antero-posterior polarity as a whole in the inducing tissue. They have made a great step forward by demonstrating that the inductor for ciliary polarity is a diffusing chemical substance, and they have already established some of its properties ; it differs from all previously known inductors in being stable to 50° but not to 100° C. It will diffuse into and out of agar. The fact that such a 'field' property as direction of beat can be determined by a diffusible chemical substance throws light on regional differentiation in general, and agrees with the latest views of such an authority as Dr. Holtfreter at the other side of the world. The British Scientific Mission has been honoured to communicate the memoirs of the Tungs to Western scientific journals for publication.

Little has so far been said in this article about the social sciences, but some distance from Appletree Rapids are a number of spacious manor-houses in the hills in which the Historical and Sociological Institutes of Academia Sinica are established. Headed by two famous scholars, Dr. Fu Se-Nien and Dr. Tao Meng-Ho respectively, they have a staff of some seventy scholars all told, thus constituting the largest institutes of the Academy. They guard indeed many precious treasures, such as some of the world-renowned Anyang oracle-bones, bamboo tablets on which the classics were written, and much of the Imperial Archives. There is even a section on physical anthropology, under Dr. Wu Ting-Lang (a former pupil of Karl Pearson and Elliot Smith), engaged in measuring the skulls excavated in association with the oracle-bones. Space is lacking to describe the concentrated atmosphere of learning which prevails in these Institutes, but those who are interested in the history of science, for example, find much willing and kindly help there. Lastly must be mentioned the existence of the National Archæological Museum in this neighbourhood, directed by Dr. Li Chi, and the Institute for the Study of the History of Chinese Architecture, directed by Dr. Liang Se-Cheng (son of the famous scholar, well known in England, Liang Chi-Chao). The section on linguistics in the Historical Institute (Dr. Li Fang-Kuei) is also interesting, with its great collections of gramophone records of dialects of all provinces of China, and song and speech of many peoples.

It will thus be seen that western Szechuan is extremely rich in matters of biological and sociological interest, even in these difficult times.

It is hoped to describe, in a later article in this series, the scientific situation in the north-west.

HISTORICAL DEVELOPMENT OF MICROBIOLOGICAL METHODS IN VITAMIN RESEARCH

By DR. MARY SANDFORD

Biochemical Laboratories, School of Medicine, University of Leeds

THE subject of microbiological nutrition, in its qualitative and quantitative aspects alike, is ever gaining increased prominence. Whereas, until some ten years ago the whole abstruse subject served merely as a minor source of contention among bacteriologists, it has now risen to an eminence sufficient to command the attention of research and other workers in several diverse fields of thought. Thus it would seem not inappropriate to outline the historical events through which these changes have been wrought.

The earliest conceptions of the nutritional fundamentals for bacteria arose as a result of the efforts of bacteriologists to cultivate organisms in chemically defined media. Until this was accomplished the study of the biochemical nature of bacteria, and particularly of diffusible substances elaborated during their metabolism, was very seriously hindered owing to the extremely complex and largely unknown constituents present in the medium. In the case of certain organisms, the provision of recognized substances (whether of organic or inorganic nature) furnishing building and energy materials, sufficed for growth ; in the case of other organisms, especially pathogenic species, cultivation was singularly unsuccessful unless small addenda of natural products were also provided. Thus there originated the belief that the addenda supplied "accessory growth factors" or "bacterial vitamins", which, it was shown, were active at extremely high dilutions and were destroyed by unfavourable conditions of heat, oxidation, etc., in the manner of the animal vitamins.

The existence of the animal vitamins was not postulated definitely before the end of the nineteenth century, although empirical methods of vitamin therapy had been known from much earlier periods. Not until about 1920, however, were vitamins isolated in pure form, their constitution determined and their synthesis accomplished. During the next phase of vitamin research the studies of pioneers like von Bunge, Lunin, Eijkman, Hopkins, Funk and others led to considerable advances, use being made exclusively of higher animals in which distinctive deficiency diseases were usually recognizable. During this same period other investigators concerned themselves with the problem of the existence and nature of "accessory growth factors" functioning in the nutrition of bacteria and yeasts. The third phase of vitamin research was initiated by a change in ideas tantamount to a revolution. It became recognized that substances hitherto found essential for the growth of lower organisms are at the same time no less important in the metabolism of higher animals. Furthermore, considerable emphasis was placed on microbiological studies owing to the great advantages to be gained.

The fusion of the two methods of approach to the study of vitamins had a very pronounced stimulatory effect on work concerning the B complex. It is notable that at least nine B vitamins are capable of detection by microbiological means. It is a reasonable surmise that if chemists had turned their attention to yeasts and bacteria instead of confining it to higher organisms, they would have had the means at their disposal to isolate all the members of the B complex in a much shorter time than was actually required[1]. Nevertheless, even though the course of vitamin research was such as to lack emphasis on microbiological nutrition, microbes have played a leading part in the isolation of six out of nine B vitamins (pantothenic acid, nicotinic acid, biotin, inositol, *p*-aminobenzoic acid and folic acid).

The history of microbial growth factors may be said to have originated in 1860–70 in the controversy between Pasteur, Liebig and Berzelius concerning the possibility of cultivating yeast in chemically defined media. It was noted that growth did not ensue from small inocula[2]. No advance was made, however, until 1901, when Wildiers, working in Ide's laboratory at Louvain, found that large seedings of yeast into certain media were able to proliferate, whereas small ones failed to do so[3]. Wildiers believed the ability to grow to be governed by the presence of water-soluble nutrient material in the large inocula. This material he called 'bios'. It is interesting that this word was coined ten years before Funk introduced 'vitamines'.

Wildiers' claims occasioned much sterile controversy during the subsequent twenty years, the existence of complex nutritional needs being absolutely denied by many workers[4]. The situation was clarified by Copping's decision in 1929 that the 'bios' requirement was governed by the type of yeast and by the composition of the medium[5]. Meanwhile Eastcott, working in Lash Miller's laboratory, accomplished a chemical fractionation of bios and isolated *i*-inositol, which was not otherwise known to be involved in nutrition[6].

Although in 1912 Funk had conjectured a relationship between the then undifferentiated vitamin B and alcoholic fermentation in yeasts, it was not until 1919 that it was suggested that vitamin B might be tested for by measuring yeast growth[7]. However, preliminary work showed that the stimulating substances could be distinguished from vitamin B_1, and the investigation which might have led to the early differentiation of the bios factors was not pursued. Similarly, other assay procedures became abortive when it was ascertained that thiamine was not responsible for the effect[8,9,10,11]; but the work was nevertheless valuable in that it developed the technique of microbiological assays.

Further advances were made possible after 1926 when crystalline vitamin B_1 was isolated from rice-bran[12], thus permitting the investigation of the effect of thiamine alone on yeast growth. Williams and Roehm in 1930[13] stated clearly that Wildiers' bios is a complex mixture of which thiamine is a single component, active in the presence of the other factors. The differences in nutrient requirements of various yeast strains were also recognized, some strains showing no stimulation by any substance readily adsorbed on fullers' earth or precipitated by phosphotungstic acid; such yeasts then cannot be stimulated by vitamin B_1.

Thus in 1930 there was forged the first link connecting the yeast vitamins or bios with the animal vitamins. Since that time many other links have been made. Pantothenic acid was discovered and isolated by its stimulation of yeasts. It was found to be identical with the chick antidermatitis factor[14,15], a factor previously differentiated from riboflavin[16] and from nicotinic acid[17,18]. Pantothenic acid was also found to be identical with a liver factor, isolated by Evans, Happold and Handley, comprising an essential nutrient for certain strains of *C. diphtheriæ gravis*[19], and with a liver filtrate factor required by rats[20,21,22]. It is now recognized as a universal cell constituent, probably common to the metabolic mechanisms of all animals.

Within the years 1939–41 three more connexions were made. Pure pyridoxin, first differentiated clearly as a rat growth-factor B_6 by György[23], was found to stimulate yeasts and therefore constituted a contributing factor to bios[24,25]. Still a further bios factor was concentrated and isolated by Kögl in Utrecht in 1935[26]. This was correlated with the animal vitamins five years later when it was shown to function as vitamin H, the vitamin protecting animals against the specific toxicity due to egg white[27,28]. Yet another link with the animal vitamins was provided when Woolley showed that inositol, known to function in bios, was required as a vitamin by at least one animal, the white mouse. It is remarkable that inositol, unlike most other vitamins, has been known chemically for decades and has only recently been acclaimed as a vitamin[29]. Such was the information which lay hidden in the problem of the nature of bios. Thus yeasts alone might have provided the means of differentiating thiamine, pyridoxin, pantothenic acid, inositol and biotin.

As great a wealth of information was, however, available from studies of other micro-organisms, including fungi and particularly bacteria. The former have not been investigated so thoroughly, but mention may be made of the early and stimulating discovery that vitamin B_1 was essential for the fungus *Phycomyces blakesleanus*[30]. This was the earliest instance of an animal vitamin being indispensable for the growth of a micro-organism, and attempts were soon made to apply the growth-response to measurements of the B_1 content of various products[31].

The volume of work carried out on the vitamin requirements of bacteria, in distinction from other groups of micro-organisms, has been enormous. The conception of essential vitamin-like factors can be traced back between twenty and thirty years. There are many instances in the literature of the need for accessory factors being noted, but little work was performed on the concentration of such factors until about 1935 and onwards. Thus the 'sporogenes vitamin' was first detected by Knight and Fildes[32] and at about the same time a full investigation of the nutritional needs of *Staphylococcus aureus* was made independently by Hughes and Knight[33,34]; in aerobic growth this organism is satisfied with nicotinic acid and vitamin B_1. The biological importance of nicotinic acid had already been shown by Warburg and Christian[35] and Euler, Albers and Schlenk[36], who demonstrated that nicotinamide was a part of the hydrogen-transporting co-enzymes. Later, Lwoff and Lwoff[37] discovered that the Warburg co-enzymes or cozymase functioned as the V factor for *H. parainfluenzæ*. At the same time as Knight was isolating the Staphylococcal factors, J. H. Mueller was concentrating factors essential for the growth of the diphtheria bacillus[38].

Following the recognition of nicotinic acid as a physiologically active substance, animal nutritionists were inspired to test this substance for vitamin activity in higher animals. Nicotinic acid and amide were found potent in curing black tongue in dogs, and nicotinic amide was also isolated from a highly active liver concentrate[39]. Other investigators reported the first successful treatment of human pellagra with nicotinamide[17]. Nicotinic acid, amide and co-enzymes I and II were afterwards found active for organisms of the dysentery group[40], lactic acid organisms[41] and *Proteus vulgaris*[42], and assay procedures based on this activity were proposed.

The components of the bios system were soon recognized to be active not only for higher animals and yeasts but also for bacteria (with the exception of inositol). Thus pantothenic acid was discovered to be required for *C. diphtheriæ gravis*, lactic acid bacteria, *Proteus morganii* and hæmolytic streptococci, and in most cases assay procedures have been proposed[43,44,45,46,47,48].

Vitamin B_6 has been found necessary for *Streptobacterium plantarum* and its use for quantitative purposes suggested[49].

Biotin has already been shown to display widespread biological activity. Besides its well-known functions as vitamin H and in bios, it is contained in the respiratory co-enzyme required by the nitrogen-fixing symbiotic bacteria inhabiting the root nodules of leguminous plants. Biotin is required by the organism *Cl. butylicum* and is known to stimulate members of the acidophilus group of bacteria.

A vitamin not previously mentioned is riboflavin. This is not a member of the bios complex, but is necessary for many higher animals and for certain bacteria. It was isolated from yeast in the form of the 'yellow enzyme' by Warburg and Christian[50]. Riboflavin is well known in the microbiological field for its growth-promotion of *Lactobacillus casei* and related organisms[51,52], this being the basis for many modified assay procedures.

Recently, another compound has been added to the list of the water-soluble B vitamins. This is *p*-amino-benzoic acid. The recognition of the growth-stimulating action of the acid is closely bound up with the theory propounded by Fildes to explain the action of chemotherapeutic agents in preventing the metabolism of pathogenic organisms. Fildes postulated that the chemotherapeutic agent threw out of gear certain enzyme systems in the parasite and that this was accomplished by virtue of the great chemical and structural similarity between the therapeutic agent and one of the co-enzymes[53]. On the basis of this hypothesis it was to be assumed that there existed in animal tissues a substance closely related to sulphanilamide, the function of which was essential to cell metabolism and which, if not capable of being synthesized by the organism itself, would be thereby classified as a vitamin. In 1940 an antagonistic action of *p*-amino-benzoic acid against sulphanilamide was noted *in vitro*[54]. Then it was found that yeast extracts would inhibit sulphanilamide activity and the suggestion was made that this was due to *p*-amino-benzoic acid in the yeast[55]. Furthermore, an *in vivo* inhibition in mice was also observed[56]. The isolation of *p*-amino-benzoic acid from yeast was soon reported[57]. The expected link with animal nutrition was forthcoming the following year when *p*-amino-benzoic acid was shown to be a chromotrichia factor for the rat and a growth-promoting factor for the chick[58]. In general the evidence so far available indicates that *p*-amino-benzoic acid is widely distributed throughout the vegetable and animal kingdoms.

Thus, it is at once apparent that no real distinction exists between the 'animal vitamins' of the B complex and bacterial growth-factors. In not a single instance has a vitamin been shown to have an action for higher animals exclusively, while the great majority, if not all, of the microbiological growth-factors are either essential in the diet of the higher animals or have been shown to be synthesized by the latter.

It is certain that the roll of known vitamins is still incomplete. When, therefore, the task of identification has been terminated, and when rapid and accurate methods of determining each member have been established, it would appear that conditions will then be most favourable for investigating the precise function of the B vitamins. It is not unreasonable to suppose that a thorough comprehension of vitamin function will constitute an advance of immeasurable value in the control of metabolic processes—normal or abnormal—in man and animals.

OBITUARIES

Prof. Susan Stebbing

DR. L. SUSAN STEBBING, since 1933 professor of philosophy in the University of London (Bedford College), died on September 11 at the age of fifty-seven at Tintagel in Cornwall. Educated at Girton College, Cambridge, she read for both parts of the Historical Tripos and for Part I of the Moral Sciences Tripos. In 1912 she graduated M.A. in philosophy, with mark of distinction, at London. After acting as director of moral science studies at Girton and Newnham, Dr. Stebbing was appointed successively lecturer, reader and professor in philosophy in the University of London.

It was unquestionably to the work of contemporary philosophers at Cambridge that the very marked bent of Prof. Stebbing's philosophical interests and orientation are to be traced. Accepting in the main the 'charter' of the scope and method for all future philosophy set out by Bertrand Russell in his Lowell Lectures, she adopted his recommendation of a piecemeal and co-operative treatment of problems by an 'analytical' method, though in the actual pursuit of this aim and in determining what this analytical method should be, she was less influenced by Russell. Here, as she herself declared, her indebtedness to Prof. G. E. Moore was the profoundest and most continuous through her life, though she also often expressed how much she owed to such other Cambridge philosophers as A. N. Whitehead, C. D. Broad, W. E. Johnson and L. Wittgenstein. Her energies were for the greater part afterwards devoted to the three fields of mathematical logic, the methodology and philosophy of the sciences, and the analysis of problems concerning perceptual knowledge of the external world.

A close and prolonged study of Russell and Whitehead's "Principia Mathematica" and of the works of most other formal logicians present and past eventually entitled her to the rank of an authority in that science. How clear and sure was her grasp of its detail is evident from the article "Logistic" contributed to the "Encyclopædia Britannica" (14th edit.) and in her "Modern Introduction to Logic" (1931)—now in its third edition—in which she skilfully combined the essentials of the newer with those of the traditional logic, and corrected and modernized the theory of scientific method inherited from Mill.

It is in this field that her best work is found, though to readers of NATURE Prof. Stebbing is probably better known as the author of "Philosophy and the Physicists" (1937), where, with much caustic comment, she rigorously examined the attempts of Sir James Jeans and Sir Arthur Eddington to elucidate the philosophical implications of recent developments in mathematical physics. Jeans's argument for the existence of a Great Architect whose activity is that of a pure mathematician and whose thoughts constitute the universe, she rejected as metaphysical extravagance. She complained that these writers, instead of enlightening the common reader, confuse him by approaching their task through "an emotional fog" and by excessive use of personification and metaphor. In the interpretation Eddington placed on his assertion that "the aim of science is to construct a world that shall be symbolic of the world of common experience", she protested at his restricting physical knowledge to the ascertainment of 'pointer-readings' and their connexions, and to his affirming an unknown background correlated with them, the existence of which, she maintained, on his own premises, he ought never to know or even suspect. She likewise objected to his regarding the laws of conservation, gravitation and Maxwell's equations as truisms and not 'controlling laws'; to his assertion that the familiar objects of perception are mere products of "mind-spinning"; to the blurred and indefinite reference in his use of such phrases as "the familiar world", "the external world", "the physical world", "the scientific world", "Nature", "the spiritual world", etc., and the failure to show how one was conceived to be related to another. She condemned, too, Eddington's frequent and large use of the metaphor of 'building' and constructing, and complained that he "nowhere expounded his philosophical ideas in non-popular language", though the communication of exact thought is impossible in inexact language.

Despite the asperity of her stricture, Prof. Stebbing's thinking throughout her writing and teaching generally was strenuous and clear-headed. She spared not herself and strove for consistency, and her judgment, if not highly original, was certainly highly independent. Her students, with whom she was very popular, and her colleagues will deeply deplore their loss. S. V. KEELING.

Sir Francis Fremantle, O.B.E., M.P.

BY the death on August 26 of Sir Francis Fremantle, Great Britain loses the services of a man who devoted the greater part of his life to the promotion of the national health. He was born in 1872, a great-great-grandson of one of Nelson's captains, and fourth son of the Hon. William Fremantle, Dean of Ripon. He chose medicine for his future profession while still a King's Scholar at Eton.

After taking honours in physiology at Oxford, Fremantle did the usual clinical appointments at Guy's, and was one of the very few men to hold both the D.M. and M.Ch. degrees, later also becoming a fellow of both of the Royal Colleges. He served as a civil surgeon in the South African War, and in 1902 acted as assistant secretary to the War Office Commission for the Reorganisation of the Army Medical Service. He then spent several years preparing for the career he had mapped out for himself already in his Balliol days—that of a medical member of Parliament. With this object in view he took the appointment of medical officer of health for Hertfordshire in 1902. He obtained leave of absence to act as plague medical officer in the Punjab in 1903 and special correspondent of the *Lancet* in the Russo-Japanese War in 1904, and to tour the Empire in 1911. He described his varied experiences in "A Doctor in Khaki" (1901) and "Health and Empire" (1911). He served in Gallipoli, Egypt and Mesopotamia in the War of 1914–18 as D.A.D.M.S.

From 1919 until his death Fremantle was Conservative M.P. for St. Albans. He soon became recognized as the leading spokesman of the medical profession in the House of Commons, and was accepted as an authority in all matters relating to the public health. From 1923 he was chairman of the all-parties Parliamentary Medical Committee. He was a member of the Industrial Health Research Board, the Departmental Commission on the Midwives Act, the Central

Housing Advisory Committee of the Ministry of Health and the Inter-Departmental Committee on Nursing.

Fremantle always tried to put before the House of Commons the strictly medical and scientific aspects of the subject under discussion. He was most conscientious, and was very regular in his attendance. Though not brilliant, he was extremely painstaking, and his opinions always received the attention they deserved. During the recent debate on the decline of the population he spoke with great earnestness on the causes and probable effects of the declining birth-rate on the future of the nation. His books brought his views on health problems before a wider public. In addition to those already mentioned, they included works on "The Housing of the Nation", in which he pointed out the shortcomings of housing as they appeared to a medical officer of health in 1927, and on "The Health of the Nation" (1928).

Fremantle was much liked by members of all parties in the House and was equally popular with all classes in his constituency, where he was D.L. and J.P. He lived at Bedwell Park, near Hatfield, and was knighted in 1932. He married Dorothy, daughter of the late Mr. H. J. Chinnery, of Bicester, in 1905 and had one son, Lieut.-Colonel David Fremantle.

ARTHUR HURST.

Prof. T. J. Jehu

PROF. THOMAS JOHN JEHU, who was born at Llanfair-Caireinion, Montgomeryshire, in 1871 and who died at Edinburgh on July 18, will be long remembered for the striking and comprehensive series of investigations he planned and carried out, in conjunction with other members of the staff of the Geological Department of the University of Edinburgh, on the metamorphic and igneous rocks of the Highland Border Series at Aberfoyle and on the Archæan complexes of the Outer Hebrides. His active life falls into three periods: (1) the period of preparation and of post-graduate research; (2) the period of his tenure of the lectureship in geology at St. Andrews; and (3) the period—from 1914 onwards—during which he occupied the regius chair of geology and mineralogy at Edinburgh.

Jehu received his early education at Oswestry High School and thereafter matriculated at the University of Edinburgh, passing through the Faculties of Medicine and Science and graduating M.B., C.M. in 1893 and B.Sc. in 1894. He was early attracted to the study of natural history and, under the inspiring guidance of Prof. James Geikie, laid the foundations of a life-long interest in geological research. He continued his studies at Cambridge, where he had a distinguished career, gaining a first class in both parts of the Natural Sciences Tripos in 1897, and a second class in the Moral Sciences Tripos in 1898, besides winning the Newcombe Prize in Natural Science at St. John's College (1898). During the tenure of a Heriot Fellowship at Edinburgh he completed a valuable bathymetrical and geological study of the lakes and rock-basins of Snowdonia and eastern Carnarvonshire, published in 1902. In 1900 he was elected to the fellowship of the Geological Society of London and in 1902 received the degree of M.D. from the University of Edinburgh.

In 1903 Jehu was appointed to the lectureship in geology at St. Andrews, where the organization of this newly established department and his lecturing and tutorial duties both at St. Andrews and at Dundee demanded most of his energy and time. He found opportunity, however, to prepare and publish two important papers dealing with the glacial deposits of northern Pembrokeshire (1904) and of western Carnarvonshire (1909), in which he discussed in detail the succession of events in the glacial history of these areas and emphasized the evidence provided by the deposits for an extension of the Irish Sea ice. In 1906 he was appointed a member of the Royal Commission on Coast Erosion and took a prominent share in drafting the reports and findings of the Commission issued between 1907 and 1911.

In 1914 Jehu succeeded his old teacher James Geikie as regius professor at Edinburgh, a position which he held until his retirement, on account of increasing ill-health, in June last. To this period belong the outstanding series of contributions to Scottish geology referred to at the beginning of this notice. Following on his discovery of fossils of Cambro-Ordovician age in the Highland Border rocks of the Aberfoyle district, first announced in NATURE of June 6, 1912, he undertook, in conjunction with Dr. R. Campbell, a detailed investigation into the geological succession and structure of this complicated region, the results of which appeared in 1917. This was followed in 1922 by his paper on the Archæan and Torridonian Formations and Later Igneous Rocks of Iona, and in later years by the extended series of researches which he carried out in collaboration with Dr. R. M. Craig on the geology of the Outer Hebrides. The "Geology of the Barra Islands" was the first of this series, appearing in 1923, and was followed by "South Uist and Eriskay" in 1925, "North Uist and Benbecula" in 1926, "South Harris" in 1927, and "North Harris and Lewis" in 1934. This sequence of papers, in which the old gneisses, the later intrusive rocks and the glacial phenomena of the long chain of islands forming the Outer Hebrides were first described in detail, represents a striking contribution to Scottish geology, and its importance was recognized by the award to the authors by the Royal Society of Edinburgh of the Neill Medal and Prize for the period 1925–27. Among the outstanding results of this extended research was the mapping in detail of a belt of highly crushed and mylonitized rock ('flinty crush') along the whole eastern boundary of the islands from Barra to Lewis, a feature which Dr. J. W. Dougal had already noted in 1911.

Jehu's tenure of the Edinburgh chair was also notable for the transference of the Geological Department from restricted and unsuitable premises in the Old College, first to temporary accommodation on the outskirts of the city in 1923, and then in 1931 to the specially designed and well-equipped Grant Institute of Geology.

Most of Prof. Jehu's research work appeared as papers in the *Transactions of the Royal Society of Edinburgh*, but he also contributed to other scientific publications such as the *Geological Magazine*, the *Scottish Geographical Magazine*, the *Transactions of the Antiquarian Society of Scotland*, etc. Before illness laid him aside, he took a prominent part in the various academic and scientific activities of Edinburgh; he represented the University, for example, on a number of public bodies, served as vice-president of the Royal Society of Edinburgh from 1929 until 1932, and was president of the Edinburgh Geological Society during 1917–18.

M. MACGREGOR.

Mr. F. F. Renwick

I JUST missed Renwick at the City of London School. He entered at about the same time as I left and had thus the good fortune to come into contact with Owen Glynne Jones, whose chemical knowledge must have proved a valuable stimulus to Renwick's interest in chemistry. After leaving, he went to the Science Section of the City and Guilds Institute at South Kensington, where he had the privilege of being under Armstrong. He was also in close contact there with Pope, with whom he remained friends for the rest of his life, and he became well acquainted with Philip, an acquaintanceship which helped to further his social development.

Renwick joined the staff of Ilford, Ltd., in 1898, but I had no contact with him until 1910, when I also joined the firm. I remember well those early days when three chemists were for some years the whole of the scientific staff of Ilford, Ltd., those three chemists being Renwick, Store, and myself. I also remember the interminable discussions, not on chemical matters but on politics and above all on religion. One of us was a broad-minded Church of England man, the second a broad-minded Unitarian and the third an Agnostic. Never did those three agree and never did they come to any conclusion, each termination of the argument leaving each of the men with his own point of view intact.

The work in those days consisted of emulsion experiments and constant work on Ilford "pinpoints". This necessitated the use of a high-powered microscope and an everlasting endeavour to recognize the minute particles, chiefly in the gelatine, which were the cause of the particular trouble under review. It was not long, however, before this work gave way to problems which were more intricate and harder of solution. Such problems included the behaviour of translution densities when in optical contact with one another, and I recall the months of argument which went on before the final paper on luminosity by Renwick, Store and Channon was published by the Royal Society.

Renwick's scientific work dealt with at least three recurrent themes. The first of these, photographic sensitometry and tone reproduction, with its fundamental problem of the significance and the measurement of photographic densities, developed stage by stage throughout his working life. Arising from that work he made, with W. B. Ferguson and D. E. Benson, the "F.R.B. Densitometer" which was to serve for many years as a standard. Armed with this instrument, he turned his attention to the broader question of photographic tone reproduction. This led him to consider the desirable sensitometric properties of photographic papers. Secondly, he made contributions to the theory of the photographic latent image. In 1920 he advanced the view that the action of light is to coagulate particles of silver present in the sensitive grains of an emulsion, so as to form a centre large enough to act as a nucleus for development. His third quest was for a photographic material, incorporating fluorescent substances, which would have a greatly enhanced sensitivity to X-rays. Using complexes of lead sulphate and barium sulphate, very efficient and relatively cheap X-ray intensifying media were produced under the names "Kryptoscreen" paper and "Brytex" intensifying leaves.

In 1922 Renwick left for the United States to take charge of the Dupont Film Factory and remained there until 1925, when he came back to England because he felt that the education of his children should take place in their own country. When he returned to Ilford, Ltd., he came as a director.

I have vivid memories of long walks prior to his stay in America. After his return he was too busy to indulge in much walking; had he been able to continue I think his health would have been the better for the exercise.

Naturally, as Renwick's responsibilities increased and the Royal Photographic Society took up more and more of his spare time, not to mention the demands of his growing family, we saw less of one another on the social side. In the latter (war) years of his life he also shouldered the added responsibilities of A.R.P. duties.

Those of us who knew him well feel that we have lost a master of photographic science who can ill be spared from the excellent work he was doing, and know that we shall not be likely to see his equal again.

O. BLOCH.

Mr. R. Borlase Matthews

WITH regret we have to record the passing under tragic circumstances of another pioneer in electrical engineering. Following a bathing accident in which his eighteen-year-old son David was drowned, Mr. Richard Borlase Matthews, who had gone to the boy's rescue, died on August 20 from the effects of shock and exhaustion.

Born in 1876, Mr. Matthews was educated at the Grammar School and Technical College, Swansea, at the Royal School of Mines, and at the Royal College of Science and Central Technical College, London. After serving his apprenticeship with the Milbrook Iron and Steel Company, Swansea, he became assistant engineer with Robert Blackwell and Co., afterwards going to the United States, where he joined the National Electric Co. at Milwaukee, then the General Electric Co. at Schenectady and later the Edison Electric Light and Power Company at Amsterdam. Returning to England, he practised as a consulting engineer in 1906, and specialized in high-voltage electric transmission, the design of power stations, and the applications of electricity to heating and domestic purposes. In 1908 he took up aeronautical work and during the War of 1914–18 he was in the Applied Design (Liaison) Department of the Air Ministry. Afterwards, on his 600-acre all-electric farm at Great Felcourt, East Grinstead, Sussex, he carried out extensive experiments on the application of electricity to agriculture, and published a number of papers on the subject. In collaboration with Dr. Ekstrom, Mr. Matthews initiated a scheme for electricity supply in the areas now served by the Mid-Lincolnshire Electric Supply Co. and in 1930 he was appointed a director of the Company.

Mr. Matthews was a Whitworth exhibitioner, a member of the Institution of Electrical Engineers and an associate member of the Institution of Civil Engineers, as well as a fellow of the Royal Aeronautical Society.

WE regret to announce the following deaths:

Dr. G. E. Pilgrim, F.R.S., formerly superintendent of the Geological Survey of India, on September 15.

Dr. F. J. W. Whipple, formerly superintendent of the Kew Observatory, on September 25, aged sixty-seven.

NEWS and VIEWS

Scientific Director of the Zoological Society of London : Prof. Edward Hindle, F.R.S.

THE appointment of Prof. Edward Hindle, regius professor of zoology in the University of Glasgow, to the post of scientific director of the Zoological Society of London, is in implementation of the policy, decided on more than a year ago, to replace the paid secretary of the Society by an honorary secretary in accordance with the practice of most learned societies. It was then foreseen that it would also be necessary to have another officer who would carry out much of the work performed by the former paid secretary. Dr. Hindle, as the first occupant of the new post now created, will therefore be mainly concerned in organizing all the more scientific branches of the Society's work, such as the scientific meetings, the publications and the library, as well as the prosectorium ; he will also deal with scientific problems concerning the collections of animals at Regent's Park and Whipsnade.

Prof. Hindle, in addition to having a wide knowledge of zoology, has travelled much and has visited most of the Zoological Gardens of the world. Since he went to Glasgow in 1935, he has taken a keen interest in starting a Zoological Park there, and is president of the Zoological Society of Glasgow, in the foundation of which in 1937 he was concerned. He is also on the council of the Zoological Society of Scotland at Edinburgh, a member of the Scottish Nature Reserves Committee, and chairman since 1935 of the executive committee of the Scottish Marine Biological Association. His many other activities include considerable editorial experience, for he is joint editor of the *Quarterly Journal of Microscopical Science* and of *Parasitology*, and sectional editor of the *Tropical Diseases Bulletin*. His research interests have been mainly in the field of protozoology, particularly infections transmitted by insects. Since 1936 he has been Lieut.-Colonel in command of the University of Glasgow O.T.C., and since the War has been in charge of the recruitment and training of potential officers in the west of Scotland. It is hoped that Prof. Hindle will be able to take up his duties in January.

Industrialization in China

THE broadsheet "Poverty and Progress in China" recently issued by Political and Economic Planning (P E P) (No. 209) gives a concise but useful account of the social and economic situation in China, wartime changes and achievements and comments on post-war industrialization. About three-quarters of China's population, or 360 million people, draw their living from about 250 million acres, or only 11 per cent of the total area of China. While much of the remainder is definitely unfit for cultivation, some part of it could be used for agricultural purposes if irrigation were provided and scientific methods of farming used. By modern standards, Chinese agriculture is heavily under-capitalized and over-manned, the Chinese farmer grossly under-fed and overworked. Excessive rents are also a serious matter, but the poverty of communications is one of the greatest causes and consequences of China's material backwardness. Most of the known mineral resources are as yet unexploited, but raw materials required for the consumer goods industries can be supplied at home and some, such as silk, wool, tobacco, leather, furs and bristles, have long formed staple exports. China became almost self-sufficient in raw cotton by 1929.

With regard to the effects of Japanese occupation, at least five of China's six major industrial regions have fallen under Japanese control, as well as the major ports, much of the road and railway network, important mineral resources and the major cotton- and wool-producing areas. The stout resistance put up in face of the invasion, however, gave the Chinese time to evacuate some of their industrial equipment to the interior, and the Government has directly undertaken industrial projects especially in heavy industry and in electricity. It has also gradually assumed control of the allocation and prices of essential materials and of the distribution of labour, but effective administrative control has been hampered by the shortage of experienced personnel, by the size of the country and the poverty of its communications and by inflation. The Chinese industrial co-operatives have played an important part in absorbing moderately skilled workers and craftsmen whose services could not be speedily utilized by the transferred private or Government industry. In regard to post-war industrialization, the broadsheet considers that industrial co-operation may have a great future in China, but will require greater support in the form of cheap credit. Technical and managerial assistance from abroad as well as machines and equipment will also be essential, but population pressure may remain the crucial problem until adjustment is facilitated by improvements in educational standards and enlightenment about family limitation.

U.S. Department of Agriculture

A SUBSTANTIAL part of Dr. Karl T. Compton's Pilgrim Trust Lecture, "Organization of American Scientists for the War", appeared in NATURE of May 29, p. 601. The Information Service of the U.S. Department of Agriculture has pointed out that some of Dr. Compton's remarks about that Department require modification. The Department's initial work was in the field of scientific research, the introduction of valuable plant species, entomology, botany, chemistry, meteorology, and so on. Its first bureau, the Bureau of Animal Industry, was created by an Act of Congress of May 29, 1884, and still carries out research in animal diseases, breeding, feeding, and management of domestic animals, and related subjects. On March 2, 1887, an Act was passed which authorized the establishment, under the direction of the land-grant colleges, of stations in each State to conduct agricultural experimentation. The Office of Experiment Stations was established in the Department of Agriculture, in 1888, to act as a staff agency to administer Federal grants involved in this and subsequent supplementary legislation, and to coordinate researches.

On December 13, 1941, a major re-organization of the Department of Agriculture was announced in connexion with the war effort ; this was validated on February 23, 1943. Seven of the old scientific bureaux and agencies, concerned largely with research work, were combined to form the Agricultural Research Administration. Included also were the four large Regional Research Laboratories, authorized in 1938, and established at Peoria, Ill., Albany, Calif., Philadelphia, Pa., and New Orleans, La. ; the nine Bankhead-Jones Laboratories for research on special agricultural projects; and the Beltsville (Md.) Research Center. At the same time, some of the Bureaux were renamed as follows: Bureau of Animal Industry, Office of Experiment Stations, Bureau of Entomology and Plant Quarantine, Bureau of Human Nutrition and Home Economics, Bureau of Dairy Industry, Bureau of Plant Industry, Soils, and Agricultural Engineering, and the Bureau of Agricultural and Industrial Chemistry. The work of the Regional Research Laboratories is now closely integrated with the last.

In addition to these agencies in the Agricultural Research Administration, the Department of Agriculture carries on considerable scientific research in the Forest Service and in the Soil Conservation Service. The Forest Service works in twelve forest and range experiment stations, and the Forest Products Laboratory at Madison, Wis.; the Soil Conservation Service investigates soil erosion and water depletion, and develops methods of soil and water conservation in co-operation with State agricultural experiment stations. Finally, the Bureau of Agricultural Economics is the central statistical and economic research agency of the Department, and has done outstanding work in social and economic science. As a result of Presidential Reorganization Plans announced in 1939 and 1940, the Weather Bureau was transferred to the Department of Commerce, the Food and Drug Administration to the Federal Security Agency, the Bureau of Public Roads to the Federal Works Agency, and the Bureau of Biological Survey to the Department of the Interior, where it became part of the Fish and Wildlife Service.

Summer School in X-Ray Crystallography

A SUMMER SCHOOL in X-ray crystallography for scientific workers in industry, which was first suggested at the second conference on X-rays of the Institute of Physics, was held in Cambridge during September 6–18. It was organized by the Board of Extra-Mural Studies of the University in co-operation with the Cavendish Laboratory and the Department of Mineralogy and Petrology. Only about one third of the applicants could be accommodated; the whole course was attended by twenty-two, and, in addition, a small number were present for one week. The main object of the course was to familiarize X-ray workers in industry with the techniques used in solving fundamental problems. Thus they should be better fitted for dealing both with the routine work in industrial organizations and with the special problems that arise from time to time. Accordingly the earlier part of the course was devoted to the study of single-crystal X-ray photographs, and possible and actual practical applications were pointed out. The orientation of diamonds in the making of dies for wire drawing and of artificial sapphires for pivot bearings were two such examples. The latter part of the course dealt mainly with powders and polycrystalline aggregates, with special reference to metals. The applications of X-ray methods to the study of equilibrium diagrams, of stress and strain, and of preferred orientation in wires and sheets, were described in detail; these were augmented by a lecture by Sir Lawrence Bragg on "The Strength of Metals". The identification of materials by the X-ray Index of Powder Photographs was also dealt with. Nineteen lectures were given altogether, by Drs. N. F. M. Henry, H. Lipson and W. A. Wooster: each lecture was followed by two hours of practical work in which assistance was given by Miss A. M. B. Parker and Dr. D. P. Riley. Since it was not possible for the students actually to use the X-ray apparatus, the practical work was based on photographs or measurements already in existence. Opportunity to see and handle the apparatus was given in special visits to the research laboratories of the Department of Mineralogy and Petrology and the Cavendish Laboratory. The course was noteworthy as an example of fruitful collaboration between industry and a university. At the present time many industrial firms make great use of X-ray diffraction methods, and at the same time, university teachers, in order to train students effectively, need to keep in touch with the practical requirements of industry.

The Cannibal Complex

PROF. J. H. HUTTON's presidential address to the Folk-lore Society deals with the subject of cannibalism (*Folk-lore*, **54**; 1943). The thesis is upheld that the origins of the practice were many and various, and that several causes were responsible for the growth of the custom among any given people. Among the reasons for the eating of his own kind by man, Prof. Hutton enumerates the following: famine, lack of meat food in the case of folk living largely on such starchy materials as potatoes and manioc, etc., revenge, and magic. In the last case ideas of sacrifice, of obtaining the life essence or qualities of the person eaten, and of getting an extra 'dollop' of soul-stuff by the same means can be traced. One is told that 'long pig' makes good eating, but Prof. Hutton does not include this possible motive. It would appear that no one of these reasons by itself is sufficient to generate the custom—indeed the fact that among some cannibals only criminals are eaten suggests that, on the whole, man does not relish eating man. When, however, several of the above factors operate, for example, when famine has started the practice, then it may develop into a custom as a result of the operation of one or more of the other motives. Such an analysis of a 'savage' practice is very interesting and helps to show the ordinary Englishman how complex are the ideas of modern primitive peoples.

The Cuscatlan Bridge in El Salvador

THIS bridge is the largest in Central America, and has been erected across the Lempa River, to complete another link in the Pan-American Highway (*Earthquake Notes*, **14**, Nos. 3 and 4; June 1943). The main suspension span of 820 ft. is carried by cables of open construction chosen to fit the unusual erection conditions. The bridge is near the base of an extinct volcano, and test borings indicated that the foundations and anchorages would be in volcanic materials consisting of cemented ash and loose boulders or stones. These materials lie in very irregular strata and pockets. Since the bridge may be subjected to earthquake shocks, special care was necessary to support the assumed earthquake forces in the design of the concrete approaches. A study of this feature indicated that multiple-span rigid-frame structures were required. A factor in the design of structures built to resist earthquakes is the natural period of vibration. Resonance must be avoided by making this different from the supposed destructive earthquake frequencies likely to arise in the district. In this case periods of from 0·5 sec. to 1·5 sec. were avoided. The natural periods of the transverse bents of the Lempa River Bridge concrete approaches is less than 0·5 sec. and that of the longitudinal frames is of the order of 0·25 sec. A factor contributing to the safety of the longitudinal frames against resonance is the varying heights of the columns, each of which has a natural period of its own different from the others. Tunnel anchorages have been used. The principal mass of the bridge is contained in the main-span trusses and the floor, and this mass would produce the greatest transverse earthquake force on the towers at the level of the trusses. The cables have a small mass but transmit heavy loads to the towers. The earthquake forces on the towers from the cables would be small, and the conservative design of the bridge was not affected by the assumed earthquake forces.

Distribution of Typhus

ACCORDING to an editorial in the March issue of the *Boletin de la Oficina Sanitaria Panamericana* the Panamerican Committee on Typhus and other Rickettsial Diseases set up by the eleventh Panamerican Congress held in Rio de Janeiro in September 1942 has come to the following conclusions. With improvement in the methods of investigation the number of cases and the extent of the geographical areas are becoming more apparent. In Chile and more recently in Bolivia and Columbia there have been several epidemics of typhus. Sporadic cases or small epidemics have been repeatedly notified in the Argentine, Brazil, Peru, Ecuador and Venezuela, while in Central America serious outbreaks have been reported in Guatemala as well as cases in El Salvador, Honduras and most of the Caribbean Islands such as Cuba, Puerto Rico and Jamaica. These diseases form one of the major health problems in some parts of Mexico and the United States, and cases have also been seen in Canada. The rickettsiases found in America may be classified into the following four groups: (1) epidemic, classic, European or louse-borne; (2) endemic, murine or flea-borne; (3) Rocky Mountain spotted fever; and (4) *Q* fever or nine mile fever, Japanese river fever or tsutsugamushi apparently not found hitherto on the American continent. The problem is particularly serious at the present time owing to the War, the rapid transportation of large numbers of persons to and from infected zones and the difficulty of enforcing maritime and aerial quarantine.

Earthquakes Registered in Spain

DURING May and June 1943, forty-five earthquakes and earth tremors were registered by the five Wiechert seismographs at the Observatory at Toledo, according to provisional bulletins just received. During May there were sixteen shocks, the strongest recording being on May 25, when an earthquake beginning with an unidentified emergent pulse at 23h. 22m. 23s. attained a maximum amplitude of 480 μ on May 26 at 00h. 09m. 17s. An earthquake with an estimated depth of focus of 230 km. began recording with *iPze* at 17h. 29m. 54s. on May 2. During June there were twenty-nine shocks registered. The greatest registration was on June 13, when an earthquake, beginning with *iPz* at 5h. 24m. 56s., attained a maximum amplitude of 270 μ at 6h. 05m. This shock had a depth of focus of 100 km. The shock of June 20, which was reported as destructive at Adapazar in Turkey, first registered at 15h. 38m. 29s. and attained a maximum amplitude at Toledo of 41 μ at 15h. 51m. (NATURE, July 3, p. 17).

Ciencia

AN editorial note in the first issue for 1942 of *Ciencia: Revista hispano-americano de Ciencias puras y aplicadas* (published in Mexico) expresses the hope that its publication, interrupted for a time, will be regular and punctual in the future. Issues for the first half of 1942 deal with a great variety of subjects, some of cultural interest, others of a practical and technical character, and in addition, it contains short items of scientific importance from a great number of countries. Of special interest is a series of articles (not yet completed) by Prof. B. Cabrera, of the National University of Mexico, entitled "El Atomismo y Su Evolucion", which provide an excellent account of the developments in our knowledge of atomic physics from the days of Democritus and Leucippus up to modern times. Dr. Honorato Castro contributes an article on the determination of the distance between two points on the earth's surface with sufficient accuracy to serve the needs of aviators. A spherical earth is assumed in the first case, and then it is shown how corrections can be applied when an ellipsoidal earth is considered. Biological and medical subjects are prominent, and among the latter may be noticed an important article by Dr. S. Obrador Alcalde, with the title, "Mecanismos Neurales De Los Ritmos Electricos De La Corteza Cerebral". The author, who is connected with the Laboratory of Medical and Biological Research, School of Medicine and Institute of Neuro-Psychiatry, Mexico, deals with investigations. These few references will suffice to show the scope of the journal, and it may also be mentioned that a considerable amount of space is devoted to reviews of scientific works.

Announcements

DR. A. H. ROSENTHAL, well known as a physicist and electronic engineer, has been appointed director of research and development of Scophony Corporation of America. Dr. Rosenthal has been connected with Scophony, Ltd., of London, for several years, and in his present position will head a group of scientific men and engineers engaged in research and development of fundamental inventions, not only in television, but also in the ever-widening field of electronics, including various applications of supersonics.

THE inaugural meeting of the X-Ray Analysis Group of the Institute of Physics will be held, by invitation of the Manchester and District Branch of the Institute, in the Physics Department of the University of Manchester on October 16. Sir Lawrence Bragg will open the meeting with a lecture on "The Physical Optics of X-Ray Analysis", which will be followed by four short papers and an exhibition of X-ray apparatus relating to industrial problems.

THE late Sir Horace Boot, the distinguished engineer, has bequeathed £5,000 to the Institution of Civil Engineers and £1,000 each to the Institutions of Mechanical and Electrical Engineers.

REFERENCE was made in NATURE of September 25 (p. 352) to the new American publication, *Mathematical Tables and Aids to Computation.* We are asked to state that the agent in Great Britain for this periodical is the Scientific Computing Service, Ltd., 23 Bedford Square, London, W.C.1 (subscription £1).

Urinary Elimination Products Following Ingestion of Nicotinamide (F_2 of Najjar and Collaborators)

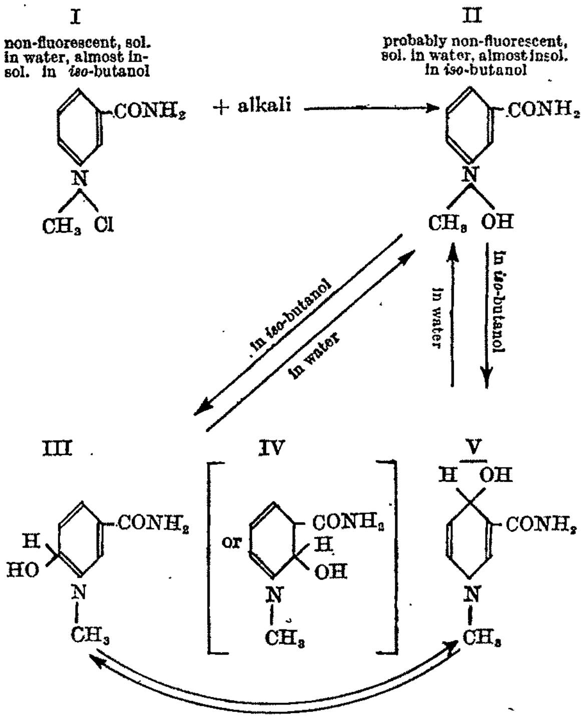
ABOUT three years ago Najjar and collaborators[1] started publishing a series of papers on two pigments eliminated respectively in urine of pellagrins (F_1) and of normal persons (F_2); the F_2 output is increased after the intake of nicotinamide and related compounds. Both pigments could be made visible by the following method. Urine was adsorbed on 'Decalso' (a synthetic zeolite), the adsorbate was eluted with 25 per cent potassium chloride and the neutral potassium chloride eluate was extracted with *iso*-butanol to obtain F_1, while F_2 was extracted after the alkalinization of the potassium chloride eluate. In long-wave ultra-violet light F_1 showed a violet and F_2 a silver-blue fluorescence. Coulson, Ellinger and Platt[2], when examining concentrates of F_2, observed a number of properties of F_2 (absorption spectrum, emission spectrum, behaviour towards hyposulphite, changes of fluorescence with the *p*H and sublimation in high vacuum) which suggested the similarity of F_2 to thiochrome. Recently Najjar, Scott and Holt[3], and Huff and Perlzweig[4], published papers on the probable nature of F_2. The former discussed the similarities and dissimilarities of F_2 to reduction products of N-methyl-nicotinamide prepared according to Karrer *et al.*[5]. The latter showed a number of properties of F_2 which were identical with those of N-methyl-chloro-nicotinamide. These publications prompted us to publish the results of the present state of our investigation.

Large amounts of urine collected after the intake of large doses (200–750 mgm.) of nicotinamide were filtered through 'Decalso' columns; the columns were eluted with potassium chloride, the alkalized potassium chloride eluates extracted with *iso*-butanol, and the dried *iso*-butanol extracts concentrated in the early experiments *in vacuo* at about 60°. Non-fluorescent solids were removed from the concentrates and the extract was taken down to a thick yellow oil which would not crystallize. Fractional sublimation in high vacuum showed the presence of at least five fluorescent constituents all of which were coloured. Filtration of the *iso*-butanol solution of the concentrate through an Al_2O_3 column revealed the presence of at least five fluorescent substances which could be separated by differential elution. The large number of various pigments suggested possible deterioration by heat, so the concentration of the *iso*-butanol extracts was carried out at room temperature. The adsorption of *iso*-butanol extracts prepared in this way on Al_2O_3 revealed the presence of not more than two fluorescent substances. One, F_{2a}, is light amber with purplish-blue fluorescence, weakly adsorbed on Al_2O_3 and quickly eluted by *iso*-butanol or chloroform. The other substance, F_{2b}, is strongly adsorbed on the top of the column; it is green-yellow with silver-blue fluorescence and quickly eluted by methanol. Neither of these fluorescent pigments is present in the original urine or in the neutral potassium chloride eluate, which is non-fluorescent. The fluorescent pigments are formed in the potassium chloride solution from a non-fluorescent precursor on alkalinization. The fluorescence of the alkaline aqueous phase is very slight. The substance causing the fluorescence is extractable with *iso*-butanol and the fluorescence intensity in *iso*-butanol is at least four hundred times as great as in the alkaline aqueous solution. In a number of fluorescent pigments which are soluble both in water and *iso*-butanol the fluorescence intensity in *iso*-butanol is about 1½ to 3 times higher than in the aqueous solution (*cf.* Ellinger and Holden[6]).

The great difference of the fluorescence intensity in water and *iso*-butanol and the extractability of the fluorescent substances from the aqueous phase by *iso*-butanol suggests the presence in water of two forms of the pigment, a non-fluorescent and a fluorescent one; the equilibrium in water is greatly in favour of the non-fluorescent modification, which contrary to the fluorescent one is almost insoluble in *iso*-butanol. Extraction with *iso*-butanol gradually transforms the non-fluorescent modification into the fluorescent one, which is accumulated in the *iso*-butanol.

Differences in *p*H, dependence of adsorption and the finding that the genuine potassium chloride eluate was non-fluorescent and became so by alkalinization excluded the possibility of the identity of F_2 with thiochrome, which cannot be formed from non-fluorescent precursors by alkalinization of a neutral solution.

The analogy with the elimination of trigonelline after nicotinic acid intake suggested the possible formation in the body of N-methyl-nicotinamide by methylation and its connexion with F_2. Two points were against this assumption: N-methyl-chloro-nicotinamide, first prepared by Karrer *et al.*[5], is non-fluorescent and, having a pyridine configuration, can be expected to show an absorption maximum around 260 mμ and not around 360 mμ, as shown for F_2 by Coulson, Ellinger and Platt[2]. Both objections were overcome, the first one by the observation that the



III, IV and V probably fluorescent, soluble in water and *iso*-butanol.

fluorescence of F_2 developed only *in vitro* and the second by the following consideration and its confirmation by the ultra-violet adsorption spectrogram.

The N-methyl-chloro-nicotinamide (I) is non-fluorescent, soluble in water with an absorption peak at 264 mμ and a shoulder at 270 mμ. By alkalinization it forms the probably non-fluorescent quaternary pyridinium base (II) with the same absorption as (I) and an additional small peak at 240 mμ, which in analogy with the findings of Decker and Kaufmann[7] and Hantzsch[8] on alkyl pyridinium bases will change by migration of the OH group into a tertiary carbaminole (III, IV or V). These will be fluorescent. In the aqueous phase the equilibrium favours the quaternary base (*cf.* absorption spectrograms). II is almost insoluble, III, IV, V are soluble in *iso*-butanol. The silver-blue fluorescent F_{2b} might correspond to III or IV, the purplish fluorescent F_{2a} either to V, according to its spectrogram and to Karrer's[5] description of the properties of *p*- and *o*-dihydropyridine derivatives, or less probably be an oxidation product of II or III, since its fluorescence resembles that of the aqueous alkaline solution of I after treatment with potassium ferricyanide.

When N-methyl-chloro-nicotinamide (I), prepared according to Karrer *et al.*[5], was dissolved in water, made alkaline, extracted with *iso*-butanol, adsorbed on Al_2O_3 and eluted with *iso*-butanol and methanol respectively, two compounds were obtained: one of amber colour and purplish fluorescence was eluted with *iso*-butanol or chloroform and another one of green-yellow colour and silver-blue fluorescence was eluted by methanol. They were indistinguishable from the two corresponding urinary compounds obtained in the same manner. The respective ultra-violet absorption spectrograms, the fluorescence concentration curves and the absorption concentration curves for 365 mμ and their reactions to alkali and acid were identical. The purplish fluorescent F_{2a} and the corresponding synthetic compound are comparatively stable to heat and acidification. They have an absorption band in *iso*-butanol with peaks or shoulders at 271, 306 and 347 mμ and an emission band between 438 and 521 mμ and a maximum at 464 mμ. The fluorescence is slightly diminished but not altered in hue by strong acid and not affected by alkali. The yellow silver-blue fluorescent F_{2b} and the corresponding synthetic compound are far less stable, more stable in *iso*-butanol than in methanol, and oxidize by standing in air, particularly when heated. They have an absorption band in *iso*-butanol with a maximum at 358 mμ and a step-out at 268·5 mμ (due to contamination with II ?), an emission band between 446 and 549 mμ with a maximum at 500 mμ; acidification with HCl shifts, in both F_{2b} and the synthetic compound, the position of the absorption maximum to 311 mμ. We have not prepared salts of F_2.

The formation of two different fluorescent compounds from the non-fluorescent precursor may explain the variation in hue of F_2 observed in routine assay, which varies from a deep purplish-blue to a light silver-blue.

F_2 appears in urine after the intake of not only nicotinamide but also of nicotinic acid, mono- and di-ethyl-nicotinamide. Ingestion of nicotinic acid and still more of mono- or di-ethyl-nicotinamide produced less and considerably more delayed and prolonged elimination of F_2 than that of nicotinamide (Coulson, Ellinger, Platt[2]). It is apparent that F_2 is formed from N-methyl-chloro-nicotinamide, and this would indicate the formation of an amide from an acid in the body, a process so far as is known without analogy.

Details of this investigation will be published elsewhere. Experiments to determine the structure of the compound are in progress.

To summarize: F_2 is not eliminated as a fluorescent pigment from the body, but formed *in vitro* from a non-fluorescent precursor by alkalinization. F_2 is composed from two fluorescent compounds which can be separated by adsorption on Al_2O_3. Substances so far indistinguishable from them can be obtained by the action of alkali from N-methyl-chloro-nicotinamide.

The authors wish to thank Messrs. Roche Products, Ltd., for the gift of nicotinamide, Dr. Edna Roe for the preparation of the ultra-violet spectrograms, and Miss M. Holden for the fluorescence measurements.

This work forms part of an investigation on nutritional deficiencies being carried out on behalf of the Air Ministry.

Digestibility of Oatmeal Phytin by Adult Man

McCance and Widdowson[1] found that adult man excreted approximately half the ingested phytin of wheaten flour unchanged in the fæces and that the phytin seriously interfered with the absorption of dietary calcium. It appeared important to us to investigate the availability of the phytin of another staple cereal, oatmeal, in adult man and its influence on calcium absorption.

Calcium, iron and phosphorus balances and the degree to which phytin is hydrolysed within the intestine were determined on four adult subjects. The general pattern of the diet was made to conform, so far as possible under the conditions of the experiment, with that found by Cathcart, Murray and Beveridge[2] to prevail in the Scottish Highlands. To keep the calcium content of the diet low, cheese was eliminated and milk intake reduced. Since the oatmeal intake in the Highlands is lower to-day than hitherto the allowance was increased to bring it closer to that consumed in the Scottish Highlands during the last century[3]. This led to a corresponding reduction in flour intake.

In the first experiment the intake of calcium was 582 mgm. and that of phytin-phosphorus 574 mgm. daily. Almost all the phytin of the diet originated from oatmeal. Only 6 per cent of ingested phytin appeared in the fæces. When calcium lactate supplements were added to the diet phytin excretions increased; when a 200 mgm. calcium supplement was added to the diet the excretion increased to 8 per cent and, later, when 500 mgm. calcium were added 23 per cent of ingested phytin-phosphorus appeared in the fæces. The increases suggest that the added calcium decreased the solubility of phytin and thus reduced the opportunity for hydrolysis. The percentages of dietary phosphorus voided in the fæces were 34, 36 and 40 during successive experiments with increasing levels of calcium intake. When these phosphorus excretions were corrected for unhydrolysed phytin it was found that phosphorus absorption was within normal ranges. It follows, therefore, that the phosphorus of hydrolysed oatmeal phytin is as available as the non-phytin-phosphorus of a mixed diet.

So far as calcium absorption is concerned our results are inconclusive. To some extent this was to be expected since calcium itself was the variable and, consequently, detection of any influence of phytin on calcium metabolism would be difficult unless such an effect were most marked. The alternative approach of varying the phytin intake by changes in the oatmeal consumption would have introduced a multiplicity of variables. Two of the subjects on the basal diet showed normal absorptions while the remaining two subjects showed subnormal absorptions. In the case of the latter subjects improvement in absorption was associated with increased calcium intake. In the former subjects the addition of calcium lowered absorption somewhat. While these results do not decide the problem of whether oatmeal phytin interferes with calcium absorption, we would like to direct attention to the long-term study of Steggerda and Mitchell[4] who, in experiments designed to determine the calcium requirement of the adult, used a diet of low calcium content in which, incidentally, more oatmeal (284 gm. of oatmeal and oatcakes) was used than in our experiments. Notwithstanding the high oatmeal intake, Steggerda and Mitchell found the daily calcium requirement for equilibrium to be 9·2 mgm. per kgm. body weight, a value agreeing well with those of Leitch[5] of 10 mgm., Mitchell[6] of 9·75 mgm. and Outhouse *et al.*[7] of 10·7 mgm. Further, recalculation of the data of Steggerda and Mitchell shows that in their experiments calcium absorption was not interfered with by the phytin of oatmeal.

The absorption of iron was higher than that found by Widdowson and McCance[8] for subjects consuming brown bread diets.

The results reported in this note strongly suggest that the digestibility of phytin, and therefore probably its effect upon the absorption of minerals, varies from cereal to cereal.

Supplies of Crystalline Vitamin D_3

In 1936, Windaus[1] and his co-workers isolated from the irradiation products of 7-dehydrocholesterol a dinitrobenzoate identical with the ester prepared almost simultaneously by Brockmann[2] from a concentrate of tunny fish-liver oil. The hydrolysates of these esters, though yielding no crystalline alcohol, clearly consisted of vitamin D_3 approaching purity. The crystalline vitamin itself was first prepared by Schenk[3] in 1937 from the irradiation products of 7-dehydrocholesterol. This isolation was described more fully by Windaus, Deppe and Wunderlich[4] in the same year. The same crystalline vitamin was prepared[5] in the following year from fish-liver oil.

A few grams of crystalline vitamin D_3, of German origin, became available in Great Britain before the War, for experimental work on animals[6] and man[7,8,9]. It was then clearly shown that clinically and in rat assays there was no significant difference between the antirachitic or hypercalcæmic activities of vitamins D_2 and D_3. The very limited quantity remaining after the completion of these experiments was set aside as a British Standard for vitamin D_3 (chick tests); since 1939, no further quantity of crystalline D_3 has been available in Great Britain.

During the last decade in these Laboratories we have had fairly extensive experience of the isolation and purification of calciferol, both on the laboratory scale and on the relatively large scale of fine chemical manufacture. During the last four or five years frequent, if intermittent, attempts have been made by us to apply these methods to the isolation of pure vitamin D_3. Even the addition of seeds of the German sample mentioned above failed to yield us any crystalline material.

It is only during the past few months that the matter has been attacked again more systematically, and we have now been able, after rigorous purification of the dinitrobenzoate, to produce several small batches of crystalline material that undoubtedly consists of vitamin D_3. One of these batches has been submitted to biological assay, and was found to have an activity slightly greater than, but not significantly different from, 40×10^6 I.U. per gram when assayed on rats by the usual line test procedure. All the batches had physico-chemical constants substantially the same as those claimed by the German investigators for the pure crystalline material.

We hope to prepare a series of larger batches, and to make a study of their physico-chemical constants, as well as of their biological activity, with the view of laying down a specification for the pure crystalline vitamin. Meanwhile, the small quantities of material at present in hand are available for research purposes and we should like this to be known to all workers in the vitamin field.

Fermented Liquors in Old-time Cooking

THE riboflavin value found in ancient buns and ale (see NATURE, September 4, pp. 273–274) has an interesting historical background. Few people realize to-day the extent to which our ancestors used fermented liquors for all manner of domestic purposes.

Out of 516 early English recipes[1] (A.D. 1430–1450), ale, vinegar and wine are given as ingredients 306 times, often two or all three together and in considerable quantities. Barm and yeast (the latter presumably yeast strained from barm) were also used, apart from their normal function in bread and cakes. Fish was almost invariably cooked in ale, vinegar or wine, and mutton was stewed with all three.

In preparing "Mawmene"[2], a mixture of finely shredded pheasant, partridge and capon, often with the addition of pork or veal, wine was added six times, vinegar twice and ale once. The dish was not so alcoholic as it sounds; it was cooked for some time and most of the spirit would evaporate, but what subsidiary food factors were left behind ?

The sauces used by our ancestors had a base of crumbled bread mixed with wine, or vinegar, and flavoured with salt, pepper, mustard, cinnamon, cloves and other spices, and many of their meat dishes were sweetened with honey or sugar comfits. Relics of these are our bread sauce with game, red currant jelly with mutton and apple sauce with pork.

A recipe of Sir Kenelm Digby (A.D. 1669)[3] for stewing rump of beef says, "and put upon it about two quarts of good strong deep well bodied claret wine". The gravy must have been rather nice ! Sir Kenelm also used elder vinegar with turkey, capon, hare, pigeon and veal, and for fattening chickens recommends that their food should be mixed with ale and adds, "and let them have strong ale to drink".

At about this same period Hannah Woolly[4], a 'domestic science' expert of her time, guaranteed to cure scurvy by steeping scurvy-grass, wormwood, horseradish, red-dock root and various other herbs in five gallons of ale, the patient to drink a pint night and morning—approximately a three weeks course. It would be interesting to know the ascorbic acid value of that mixture.

Hannah Glasse[5] (A.D. 1747) used port and sherry on all possible occasions, stewed her steak in ale and, in a chapter headed "For Captains of Ships", gives a recipe for mushroom catchup to keep twenty years, which starts "Take a gallon of strong stale beer. . . ."

In the early eighteen hundreds, pickled herrings were still a national dish, great quantities were eaten, and there was a thriving Scottish trade in salmon pickled in vinegar, which was exported to the growing industrial towns of the south[6].

These delectable habits died rapidly during the second half of the nineteenth century. Quick transport from the developing railways, the drift of population to the towns during the Industrial Revolution, the growth of vast suburbs with cramped kitchens (later to become our slums), the invention of canning plus the demand of an industrial people for ready prepared foods, most of all, possibly, the ever-increasing excise on fermented liquors and the decline of home brewing—all these played a part in the change.

Whether the result has been for the nutritional benefit of the nation as a whole is open to grave doubt.

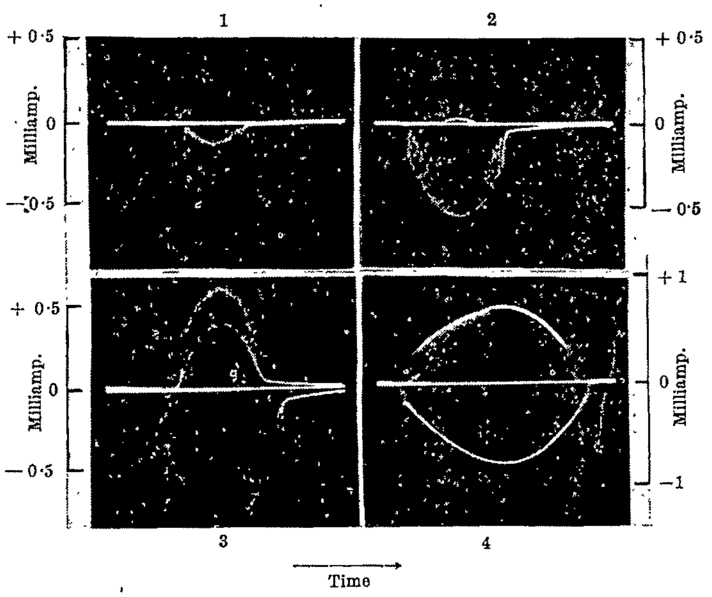
Initiation of Glow Discharges

THE form of the breakdown voltage/pressure curve for various gases in the pressure range 0–5 cm. mercury has been established by several investigators. The breakdown voltage usually measured is that at which a galvanometer in series with the experimental tube indicates a current of 0–1 microamp. This current increase is usually so abrupt (Druyvesteyn and Penning[1], p. 105 and Fig. 16) that the corona-starting voltage is defined within a range usually smaller than the accuracy of measurement. Huxley[2,3], Penning[4], Bruce[5] and Boulind[6], among others, have studied He,Ne[2] and N_2[3], A,He,Ne[4], H_2[5], and O_2, CO_2, H_2 and air[6].

There has been little published work dealing oscillographically with the breakdown processes at these pressures[7] (less than 5 cm. mercury). Considerable information is available for air at atmospheric pressures[8,9,10], and more recently, after our own experiments were started, data have been obtained for He, N_2 and A[11] at pressures down to 10 cm. mercury.

Owing to the present circumstances, the time available for our studies has been limited, and the gases used (H_2, N_2, O_2, A, Ne, CO_2, CH_4, air and CCl_2F_2) have usually been of commercial purity. Mercury contamination has been carefully avoided. However, the results obtained with these gases have been so varied and reproducible that some conclusions may be drawn for the pressures less than 3 cm. mercury. Also, the use of alternating current (50 c.p.s.), which is unusual in work of this kind, has been found advantageous and has led to certain improvements in technique. Other earlier workers[12,13] have used A.C. in corona studies carried out before modern methods were applied in this field. Care must clearly be taken in the interpretation of the results, so that effects due to the A.C. are not attributed to discharges in the gases. The A.C. results have, therefore, been checked frequently with D.C., and it is unlikely that any but very minor effects are due to the use of A.C. However, the persistence of metastable atoms in argon apparently causes small currents to flow during the positive half-cycles if appreciable currents are established during the preceding negative half-cycles. This causes the A.C. peak breakdown voltages in argon to be consistently less than the corresponding D.C. breakdown values; whereas in the other gases, the A.C. and D.C. breakdown voltages are identical, within the limits of experimental error. In accordance with the earlier work[4], negative breakdown precedes positive breakdown at the smaller electrode; the only exceptions we have found are oxygen and air at certain pressures in the counter, again confirming established data[6].

The use of a two-beam oscillograph, which allows



simultaneous observation of tube current and either tube voltage or a timing wave, has been found to be of great assistance.

Figs. 1–4 show the results for O_2 ($\sim$ 0·5 per cent N_2) at a pressure of 1·5 mm. mercury and a temperature of approximately 20° C. in a Geiger counter the copper cylinder and tungsten wire diameters of which were respectively 2·5 cm. and 0·127 cm. The resistance in series with the tube was approximately 1·9 megohms, except for Fig. 4, where it was 1·1 megohms. Variation of this resistance has often a considerable effect on the nature of the corona phenomena, as would be expected. Figs. 1–4 were taken respectively for tube voltages of 560, 640, 735 and 1,200 peak volts. At the lowest voltage only negative corona is present, in the form of negative streamers which, as the voltage is raised, eventually give place to a steady conducting state, in this case a self-maintained glow discharge. Positive corona appears initially as a continuous discharge (Fig. 2); positive streamers develop at higher voltages and are finally succeeded by a glow discharge (Fig. 4).

In some cases, streamers occur at breakdown and persist for an appreciable range of voltages. It would appear[14] that many of the authors cited above had made no allowance for this possibility in calculations involving the use of steady current values.

These experiments will be continued and extended, as circumstances permit, although it is inevitable that progress will be slow. It is hoped in particular to study the discharge in carefully purified gases and, extending Weissler's results, to observe the effect of the addition of quenching agents to gases in which metastable states appear[11]. Interesting features of the discharge centre round the Paschen minimum, where the effect of electrode materials will no doubt be important, and this region requires to be investigated further. The transitions between the various forms of the discharge, for example, from the streamer to the continuous glow, all require a closer investigation, and this will, of course, necessitate a careful study of the effect of the circuit parameters. Then, in addition to the low-pressure observations, it is hoped to observe the discharge effects at high gas pressures, in excess of atmospheric, some results for which have been obtained by Pollock and Cooper[15].

One of the valuable features of work on corona is the contribution to the better understanding of the fundamental processes which govern the propagation of discharge in gases and, in particular, photo-ionization. Such knowledge is necessary for the interpretation of many discharge phenomena, such as the spark, the mechanism of streamer development, and Geiger counter action.

Among other investigations which are of direct practical use to the engineer, and which we hope to continue, is the study of corona in various types of engineering apparatus, where corona may take place either in a gas, liquid or solid dielectric. Similar work on the onset of ionization has been reported by Quinn[16].

We are indebted to Dr. A. P. M. Fleming, director of the Research and Education Departments, Metropolitan-Vickers Electrical Co., Ltd., for permission to publish this note.

Future of Technical Colleges

WE have read with interest the communications by Mr. E. B. Moullin[1] and Dr. H. Lowery[2], which comment upon our letter[3] on this subject. These letters fail to offer further constructive suggestions, and we therefore focus attention again upon some essential and immediate needs of technical education, particularly in the advanced sphere, and upon a scheme for their fulfilment. We would urge that so far as possible, discussion should be concrete and definite. It is not enough to speak vaguely of ideal systems, people's university, etc., without specifying what is meant, or how to attain this ideal.

It has been contended that[2] in relation to the total number of students receiving technical education, there are not many who require advanced training in applied sciences, technology and commerce. The *absolute* numbers, however, are not small, and are steadily growing. In the present chaotic organization of technical education, whereby both advanced and elementary students are frequently housed in the same college, the great numbers of elementary students statistically outweigh the advanced students. Imagine the same system to operate in the university sphere, with elementary education and also advanced academic studies in the same building. From the point of view of numbers, the elementary students would again numerically far outweigh the advanced students. In fact, in the technical colleges as in the universities, and for the same reasons, the advanced work is of vital importance. We would again urge the creation of higher technical colleges in which the advanced work at present in existence may be concentrated. The major colleges might be fed partly by satellite colleges, and also by technical schools, evening institutes and schools, just as the universities are now fed by the high schools, grammar schools and public schools. The advanced work at present done by the technical colleges, particularly on the research side, is inadequate ; but with the suggested arrangement a growth of advanced technology and research becomes possible.

The new higher technical colleges, or institutes of technology, functioning along these lines, with generous financial backing by the State and, we would hope, by industry, have a vital part to play in maintaining the place of Great Britain as an industrial country. We would again point out, since this great but remediable weakness in our technical education system has not been emphasized sufficiently, that the apex of technical education, as understood in America and the Continent, and exemplified in their institutes of technology and *technische Hochschulen*, is almost entirely lacking in Great Britain. One reads, moreover, that Britain spends only a very small fraction *per caput* of the American and Russian expenditure on technical education. To hold our own in post-war industrial development requires great and unremitting efforts on our part. Nowhere can we begin better than by sorting out our technical education system, concentrating the various grades of work in appropriate institutions, and by creating some institutes of technology on the American pattern.

We are loth to make an issue of external examination systems. As a means of obtaining high qualifications in technology, we believe that the external degree system has rendered important service to Great Britain, whatever has been said to the contrary by those who disparage degree work in technology in the technical colleges. We make the further comment that before the external degree could be displaced it would be essential that an internal examination *accepted nationally by industry and commerce* as giving qualifications at least of equal standing should be *actually in existence* to take its place. We know of no such examination which is even remotely able to substitute for the external degree examination in giving an all-round qualification in the various applied sciences. One can therefore see that any attempt to suppress this system constitutes a serious threat to training in advanced technology in technical institutions. This threat comes, moreover, at a time when we should be making every effort to expand and develop all branches of technical education, particularly the advanced work.

[2] NATURE, 152, 218 (1943).
[3] NATURE, 152, 80 (1943).

DR. LOWERY's letter in NATURE of August 21 contains several statements which cannot be allowed to pass unchallenged.

Referring to degree courses, he writes, "It is not right, however, that the coaching of a relatively few people for examinations run by an outside body . . . should come to be regarded as the highest function of a technical college and should unduly influence its educational aims". I am quite certain that, in general, it is not so regarded either by technical colleges or by the members of the public who know of their work, and the implication that this small volume of work unduly influences the educational aim of colleges is quite incorrect. Further, he states, "Degree courses in technical colleges are makeshift courses", but Dr. Lowery is quite well aware that there are many technical colleges where the degree courses are not makeshift courses but are properly organized courses conducted by staff, and with equipment, not inferior to some universities. Dr. Lowery should in fairness to these colleges have qualified the sweeping character of his statement.

The question of the desirability of technical colleges conducting any degree courses may be debatable—though the real debatable point is should there be such a thing as an external degree—but to imply that technical colleges are "tending to neglect their most important work" partly as a result of "flirting" with university education is to convey a wholly misleading picture of the technical colleges in Great Britain. The splendid work of these colleges, related directly as it is to the needs of industry, has been a factor of the greatest importance in our industrial development.

D. S. ANDERSON.
(Principal.)

Birmingham Central Technical College.

THE attention of the Council of this Association has been directed to a letter from Dr. H. Lowery which appeared in NATURE of August 21, p. 218. In this the writer states that: "Degree courses in technical colleges are makeshift courses, and have grown out of a makeshift system".

While it is true that these courses have grown, as indeed the universities have themselves, from small beginnings, the statement that the degree courses in the technical colleges of Great Britain are makeshift is quite untrue and a damaging statement as regards many important colleges in both London and the provinces.

In London, several of the polytechnics are recognized for *internal* degrees of the University of London in a number of subjects. Actually, about 44 per cent of the students who obtain the internal degrees in engineering carry out their courses in polytechnics and not in the University itself, while in science the percentage is about 27.

There are also a number of well-equipped and adequately staffed technical colleges in the provinces which have been carrying on degree courses successfully for many years. These courses are in every way as satisfactory as those in the universities themselves.

PRECISION HYGROMETRY WITH A WET-BULB

By Dr. W. LAWRENCE BALLS, C.B.E., F.R.S.
Cotton Research Board, Giza, Cairo

A METHOD was required whereby the relative humidity (R.H.) of air in equilibrium with cotton samples could be determined to one half of one per cent. The apparatus had to maintain its zero and its calibration year in and year out, so as to make it suitable for routine employment in a testing laboratory. Certified thermometers which are used within the limits of ordinary room temperature changes can fulfil this condition, so the wet-and-dry-bulb method was investigated and improved until it became precise. So far as cotton-testing is concerned, the work is at present in suspense, but the wet-bulb hygrometer was tried out during a couple of years and seems to merit description.

The following are the essential components. An aspirator, which is a diaphragm-type variable speed air-pump, is required if re-circulation of the air is needed. The temperature of the air at the sampling point is noted by a thermometer mounted with its bulb concentric to the intake of the aspirator. This air then passes through a long coil of copper tube immersed in a water-bath, where it comes to the temperature of the water and so almost stabilizes the next reading to be taken, that of the dry-bulb proper; incidentally, this minimizes reading errors on the dry-bulb. This partial stability is only due to the large volume of the water-bath (about ten litres), its temperature not being regulated at all; obviously, if its temperature is below the dew-point of the incoming air, warm water must be used. The wet-bulb and dry-bulb thermometers are mounted inside two vertical and parallel glass encasing tubes, sealed below and stoppered at the top, with side-tube inlet, side-tube exit, and a side-tube connexion between them. The lower ends and the side-tubes are all immersed in the water-bath, thereby helping to screen the thermometer bulbs from external radiation. Air coming from the copper pipe impinges on the dry-bulb at right angles through the inlet tube, then passes through the interconnecting tube; cemented inside this is a stainless steel liner which standardizes its diameter and hence the rate of flow at which the air impinges on the foot of the wet-bulb in the other encasing tube. The air escapes from the latter through the exit side-tube, which is similarly lined, but with a stainless steel tube of slightly smaller diameter; thus a small air pressure is built up in the wet-bulb encasing tube; this exit tube is aligned to withdraw the air from the top of the wet-bulb wick, so giving very turbulent air-flow over the wick at a known final velocity; actually six metres per second is used. The volume of air passed through or around the circuit is indicated by a venturi throat inserted therein with an inclined mercury manometer attached; this is calibrated by direct collection of the air discharged and adjusted by inclining the manometer so that a single marked point thereon indicates six litres per minute in our particular lay-out; if the reading is off this marked point, the pump-speed is regulated accordingly.

Certain precautions are taken in the use of these essential components. The encasing tubes and venturi meter are enclosed in a glass-fronted cupboard resting on top of the water-bath tank; the roof of the cupboard is hinged for access to the encasing tubes. Thermometers of the sling-psychrometer type are used, with small cylindrical bulbs, taking less than two minutes to reach equilibrium; the lapse of this time is most conveniently indicated by using a sand-glass, to avoid confusion of thermometer figures with clock figures in rapid working. This type of thermometer was more easily obtained in Fahrenheit calibration, and is read to estimated tenths of a degree Fahrenheit in order to get the accuracy required; this is done by simple lenses in anti-parallax mountings, which slide on the glass cupboard-front. It having been found that confusion was liable to happen between tens and fives on the scale of degrees when reading through lenses, the thermometer stems were painted red from 65 to 70, 75 to 80, and so on. A very convenient standard wick was adopted by removing the braided cotton cover from electric wiring flex of suitable size; this was boiled in caustic soda and washed with distilled water while stretched on glass tubing of the same diameter as the thermometer bulb; after drying, it was cut into lengths slightly longer than a bulb, slipped on the bulb and slightly stretched to make it hold closely.

With the apparatus thus set up, and using appropriate tables or graphs, we first obtain the 'grams of moisture per kilogram of air' from the depression of the wet-bulb, and then refer this to the temperature of the intake thermometer, so finding the relative humidity at the intake. The standard error of the determination is dependent on reading the thermometers to one tenth of one degree, and so is greater with damp cold air than with hot dry air; this error can be reduced by using a warm water-bath, and in average conditions is less than $\frac{1}{2}$ per cent R.H. The absolute accuracy of the result, as distinct from the relative accuracy with which we were immediately concerned, is necessarily contingent on the accuracy of the tables of hygrometry. In the last resort, these should be worked out anew for the particular instrument design employed, with the correct air-speed.

However, the lay-out described, though completely standardized, can only be effective if the evaporating abilities of the wick itself are also standardized, and the technique whereby the wick-properties are stabilized over periods of a year and more constitutes our principal improvement in wet-bulb hygrometry. It has been noted by meteorologists that wet-bulb wicks deteriorate during use, the depression becoming less than it should be. This had been ascribed to dust and dirt adhering to the wick. A weekly change of wick is routine in some meteorological screens. Using our apparatus under the very stringent conditions of cotton-air-moisture determination checked against actual oven-tests, on many samples every day, we found at first that a weekly change of the wick sufficed. But this was during the winter, in Alexandria, and as the observations continued into the hot weather we found evidence of wick deterioration arriving more rapidly, until by June the results were falsified even by the second day of use. This suggested a biological factor in the deterioration.

The encasing tube of the wet-bulb thermometer was therefore expanded into a biggish bulb at the bottom, this bulb being completely immersed in the water-bath, and itself filled with a 0·1 per cent solution of mercuric chloride, as an antiseptic against bacteria and fungi, which nevertheless was so dilute as not to behave unlike pure water during short runs. The stopper at the top of the encasing tube was expanded into a glass saucer, closed by a thin and slack rubber diaphragm from toy balloons. The wet-bulb thermometer was suspended from this diaphragm with appropriate stops to limit its range of up and down movements. Normally it remained with its bulb immersed in the mercuric chloride solution. When the air-pump was started the small pressure built up in the encasing tube caused the diaphragm to distend; this lifted the thermometer with its dripping wet wick into the turbulent air-flow and held it steady in position ready for reading after two minutes had elapsed. The wicks used will hold the depression constant for some five minutes or more, according to conditions, before they show signs of drying up. The evaporation from the solution is negligible except while the air-stream is flowing, and it is then of the order of three milligrams of water per test, so that the solution has eventually to be topped up with distilled water; actually about once a week when in continuous daily use. The relative humidity of the outgoing air is perceptibly increased by this added water, which is immaterial unless re-circulation is employed, when small corrections become necessary, dependent on the volume of air in the system.

The stability of the system over long periods of time, and its low standard error, are its outstanding advantages. Its accuracy would seem to be of the same order as that of the more difficult dew-point determinations. Additionally, it is often very convenient to be able to place the intake in some particular locality, with a long rubber tube to the apparatus, and examine the humidity in different parts of a room, or underground in the soil, and so forth.

ROYAL PHOTOGRAPHIC SOCIETY'S ANNUAL EXHIBITION

THE eighty-eighth Annual Exhibition of the Royal Photographic Society of Great Britain was opened on September 3 by H.R.H. King Peter of Yugoslavia. The Exhibition is being held at the Society's premises at 16 Princes Gate, London, S.W.7, and will be open to the public between 10 a.m. and 5 p.m. until October 23 inclusive. A new experiment being tried this year is Sunday opening. The Exhibition is being opened on alternate Sundays, September 12 and 26 and October 10 from 2 p.m. until 5 p.m. This is to enable members and others who, on account of their war work or other causes, are unable to travel or find time to see the Exhibition on weekdays.

The Exhibition, as is usual, covers all branches of photography from the purely pictorial to the use of photosensitive material in research. While one cannot but admire some of the pictorial work and note that both the quantity and quality of previous years seem well maintained, one can regret that the same cannot be said of the 'scientific' exhibits. The best represented section is probably "Natural History", in which are shown many fine examples of wild life (both plant and animal) in their natural habitats. The War has evidently had little effect on the patience of the photographer of Nature.

Colour photography also seems to have suffered little, being represented by a number of prints on paper some of which are of excellent quality. Many transparencies are shown, including one case of "Scientific Colour Transparencies" which are mainly of biological subjects, or photomicrographs by polarized light.

Of special interest this year are two exhibits in the Trade Section. One is on mass miniature radiography by Ilford Limited and the other on the 'Kodak' transfer sensitizing process. The attack on tuberculosis depends for its success on early diagnosis, so that the possibility of mass miniature radiography should be a milestone on the road to the control of the disease. In the absence of means of refracting or specularly reflecting X-rays it has been generally necessary to obtain full-size pictures of the subject. Quite apart from the cost of such large photographs as are necessary when dealing with the human chest, the handling of large numbers of 15 in. × 12 in. films becomes a serious matter. The possibility of photographing, with an ordinary camera and film sensitive to light, the fluorescent image produced by X-rays falling on a fluorescent screen was shown many years ago, but it has only relatively recently been possible to reduce this process to one of routine requiring only a short exposure of the patient to X-rays. This development has been due largely to the increase in aperture of lenses and the increase in speed of photographic film. The image of the chest is contained in an area of film only one inch square, so that a large number can be accommodated on 35 mm. cine-film which can be easily handled in any length.

Mass miniature radiography units have been developed and have been adopted by the Ministry of Health for national service purposes. The equipment and method of working is illustrated in detail by pictures and models. It must be emphasized that the method is not intended as one for diagnosis but to enable a large number of presumably normal individuals to be examined to detect unsuspected abnormalities which can, where necessary, be the subject of full-scale radiological and clinical examination.

The exhibit by Kodak Limited is of the 'Kodak' transfer sensitizing process by means of which any flat sheet material can be sensitized. The chief application is in the marking of templates. The conventional method consists in hand-scribing the design from a scale drawing, which requires a skilled and experienced operator. By the method illustrated the material on which the template is to be marked is first lacquered and the sensitizing paper is then squeegeed to it by means of a roller squeegee. The temporary paper support is stripped off when the sensitive surface is required for use. The required design may be drawn on translucent paper, or should the original drawing be on an opaque support an intermediate negative is necessary or the 'reflex transfer' process may be used. The exposed layer is then developed on the metal or other support to yield an image of the required design.

The process is illustrated by a series of specimens contributed by Handley Page, Ltd., including an 8 ft. × 4 ft. metal section bearing designs reproduced by this process.

The process also lends itself to the production of such things as name-plates, instrument dials, etc. Direct use may be made of the photographic image, but more robust forms may be made by converting the image into a gelatin stencil which allows the undercoat lacquer to be dissolved away, leaving the design in lacquer, or the bared metal may be plated or etched and filled. Typical examples of this application are shown by Marconi Instruments, Ltd., and The Accurate Recording Instruments Co.

Having dwelt at some length on only two of the exhibits may give the impression that there is little else to be seen. This is not so. The pictorial prints, lantern slides and stereoscopic transparencies are themselves worth a visit and can be relied upon to provide agreeable relaxation.

A SURVEY OF CANADIAN SCHOOLCHILDREN

THE statistical results of a survey of children in the elementary schools of the city of Toronto, taken in November 1939, have recently been published*. It is a team work in which the Hospital for Sick Children in Toronto, the Department of Pensions and National Health, Ottawa, the Education Statistics Branch of the Dominion Bureau of Statistics, and the Toronto Board of Education participated. The whole report is the work of Mr. N. Keyfitz and his assistants of the Social Analysis Branch of the Dominion Bureau of Statistics.

In 1923 the Department of Public Health in Toronto made a survey of 59,000 elementary pupils, from which a table of average heights and weights by age was calculated and which became the standard for Canadian school-children. During the intervening sixteen years it was found that, as a result of the policy of social improvement based on the previous findings, pupils in the various age-groups were outgrowing their categories, and it was decided to institute a new survey in which medical investigation would be as thorough as possible and the correction of physical defects would be a major aim.

In the present study of 78,000 children, equally divided on the basis of sex, emphasis is laid on the influence of such factors as economic status, birthplace of parents and the range within which nutrition affects the build of children. An effort is made throughout to determine the relative importance of the following points: (1) Does the economic status of the family influence the prevalence of disease and defect? (2) Does it retard the child in his academic standing as indicated by his school grade? (3) Do certain combinations of defects or diseases have more effect on the height and weight than the same defects and diseases unassociated? (4) How does heredity as shown by parental birth-place affect build?

The pupils of 1939 are found to be taller for their age than similar groups of 1923, except the six-year-olds. This may be explained by the fact that it is now customary to enter children at school at six, while formerly less robust six-year-olds were kept at home. Girls are found to mature earlier than boys; but thirteen-year-olds of the latter are found to mature at two different rates, as shown by a bimodal distribution representing maxima in height and weight combined.

An interesting comparison between the Toronto survey and Sir Frederick Menzies's London survey of 1938 is made. Canadian children, as one would expect, are taller than English ones. The London children of 1938 approximate in height and weight the 1923 levels of Toronto. However, the differences between the well-to-do and poorer metropolitan boroughs show the same tendencies as the Toronto ones, the differences being, if anything, less marked in England. A similar extensive study by the U.S. Department of Agriculture (Garment and Pattern Construction) in 1941 of 147,000 white schoolchildren of 4–17 years of age is remarkably close to the Canadian figures.

Economic status of parents: It is found that unskilled labourers and unemployed parents have children who are under-height; but there is striking absence of differences in build, that is, weight in relation to height, between children from poor and prosperous districts.

Diseases and defects: Diseases have no appreciable effects on height and weight, but defects tend to make their owners shorter and lighter for their height, that is, thinner.

Heredity: Children of United States-born parents are taller, and those of British-born parents are lighter than those of Canadian-born parents. Inter-racial marriage tends to increase the height of offspring. Children whose parents are eastern European-born are taller and those whose parents are of western European birth are shorter and heavier.

It is, of course, well known that foreign-born immigrants tend to be in less skilled occupations, while United States-born are often in a higher economic level than the Canadian-born.

The work is lavishly illustrated with charts and tables but one feels, after all is said, that fewer tables and a more detailed discussion of the biological principles governing growth would make this excellent booklet more valuable and instructive. Nevertheless, in these days when the very basis of science is being challenged, and men of science are everywhere engaged on the destructive aspects of their calling, it is refreshing to come across a progressive little book of the type, at once creative and far-sighted.

R. E. G. ARMATTOE.

RADIO DETECTION AND RANGING

'RADAR', the code name for radio detecting and ranging, has been officially revealed to be one of the foremost scientific developments of the War, according to a statement issued by the Western Electric Co. (*Bell Lab. Rec.*, 21, No. 10; June 1943). An electronic instrument projects a beam of radio impulses, and these impulses reveal the presence of distant objects by rebounding to the observer. When trained on enemy aeroplanes, still so distant as to be beyond the reach of anti-aircraft guns, 'radar' reports their presence. The system is, of course, unaffected by darkness, clouds or fog.

Under the name of radiolocation the method was credited by Lord Beaverbrook with winning the Battle of Britain. In the South Pacific, according to the article in the *Bell Laboratories Record*, it has been responsible for enemy losses of millions of dollars' worth of ships, aeroplanes and submarines. Radar was developed on the basis of years of research and experiment in electronics, independently in the United States and Great Britain, and credit for the development must be shared by many of the foremost scientific men of the two nations.

The fact that radio waves can be reflected just as can light and sound waves had long been known and the phenomenon had been used, for example, to measure the electrical reflecting surface in the ionosphere. Only with the advent of the ultra-short radio waves in the early 1930's did it become possible to observe reflexions from objects so small as an aeroplane. In 1932, it was noticed that an aeroplane flying about 1,500 ft. overhead produced a noticeable 'flutter' of about four cycles per second. In 1938 the absolute altimeter was introduced commercially for use in aircraft. This instrument employed the principle of directing radio waves against the ground and timing their return to give the exact height of an aircraft above the earth. In the same year, in the United States, a series of experiments at 15th Street in Brooklyn overlooking the Narrows leading into Manhattan's upper bay was made, using a modification of the absolute altimeter enclosed in a hornlike directional antenna system of galvanized sheet, and it was observed that radio waves directed against ships passing through the Narrows were thrown back into the receivers.

With the formation in the United States of the National Defense Research Committee, 'radar' became one of the most active lines of investigation by a large group of scientific workers. A mission of British men of science to the United States made a complete disclosure of the status of their art, with reciprocal disclosures by the N.D.R.C. group. Still in limited use in the U.S. Armed Forces when the United States entered the War, 'radar' is now standard equipment for both American Army and Navy. An official statement says of it, "radar is used by static ground defences to provide data for anti-aircraft guns for use in smashing Axis planes through cloud cover, and by airplanes and warships".

FORTHCOMING EVENTS

*(Meeting marked with an asterisk * is open to the public.)*

Saturday, October 2

Association of Scientific Workers (at Essex Hall, Essex Street, Strand, London, W.C.2), at 2.30 p.m.—Conference on "Problems of Freed Europe—The Challenge to the Medical Sciences". Problems of the Occupied Territories: Belgium (Dr. A. Marteau); Czechoslovakia (Dr. V. Kruta); Greece (Dr. A. P. Cawadias); U.S.S.R. (Prof. S. A. Sarkisov); Present Plans for Relief (Prof. J. R. Marrack).

Geologists' Association (at Geological Society, Burlington House, London, W.1), at 2.30 p.m.—G. S. Sweeting: "Wealden Iron Ore and the History of its Industry".

Monday, October 4

Society of Chemical Industry (London Section) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2.30 p.m.—Mr. S. J. Johnstone: "The Organisation and Use of Technical Intelligence Services".

Tuesday, October 5

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 1.30 p.m.—Dr. Margaret Mead: "Modern Anthropology".

Chadwick Public Lecture (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 2.30 p.m.—Mr. E. J. Boome: "Muscular and Mental Relaxation in Peace and War".*

Society for the Study of Inebriety (in the Meyerstein Lecture Hall, Westminster Hospital Medical School, Horseferry Road, London, S.W.1), at 4 p.m.—Dr. A. Ninian Bruce: "Alcohol and Avitaminosis" (Nineteenth Norman Kerr Memorial Lecture).

Society of Chemical Industry (Manchester Section) (Joint Meeting with the Manchester Literary and Philosophical Society) (in Room 7, The University, Oxford Road, Manchester), at 5.30 p.m.—Sir John Russell, F.R.S.: "Agricultural Reconstruction in Europe after the War".

Thursday, October 7

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Colonel Sir A. Stanley Angwin: Presidential Address.

Friday, October 8

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. H. W. Newton: "Solar Flares and Magnetic Storms".

Saturday, October 9

Sheffield Metallurgical Association (Joint Meeting with the Microchemical Section of the Society of Public Analysts and the South Yorkshire Section of the Royal Institute of Chemistry) (in the Department of Applied Science, The University, St. George's Square, Sheffield), at 2.30 p.m.—Symposium on "Microchemical Analysis".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Chair of Social Medicine—The Secretary, The University, Edmund Street, Birmingham 3 (March 1).

University Lecturer in Anthropology—The Secretary of the Appointments Committee of the Faculty of Archæology and Anthropology, Museum of Archæology and of Ethnology, Cambridge (April 15).

Head of the Department of Dyeing in the Bradford Technical College—The Director of Education, Town Hall, Bradford (October 9).

Lecturer in Physiology and Zoology—The Registrar, Technical College, Sunderland (October 9).

Lecturer (woman) in Biology in the Department of Pharmacy and Biology—The Principal, Central Technical College, Suffolk Street, Birmingham 1 (October 9).

Educational Psychologist—The Chief Education Officer, Education Office, Warrior Square, Southend-on-Sea (October 11).

Research Histologist (non-medical) in the Pathological Department—The Secretary, Royal Cancer (Free) Hospital, Fulham Road, London, S.W.3 (October 13).

Teacher of Mathematics and Physics in the Junior Technical School and Senior part-time Classes of the Batley Technical College—The Director of Education, Education Offices, Batley, Yorkshire (October 15).

Assistant Electrical Engineer for the Nigerian Government Public Works Department—The Secretary, Overseas Manpower Committee (Reference No. 538), Ministry of Labour and National Service, Alexandra House, Kingsway, London, W.C.2.

Assistant Mechanical Engineer for the Electrical Branch of the Nigerian Government Public Works Department—The Secretary, Overseas Manpower Committee (Reference No. 1076), Ministry of Labour and National Service, Alexandra House, Kingsway, London, W.C.2.

Mechanical and Electrical Engineer for the Gold Coast Government Public Works Department—The Ministry of Labour and National Service, Central (Technical and Scientific) Register, "D" Section, D.588X, Alexandra House, Kingsway, London, W.C.2.

Engineer and Manager of the Inverness Corporation Electricity Department—The Town Clerk, Town House, Inverness (October 11).

Assistant Master to teach Science, with an Engineering bias, and Practical Mathematics, in the Forest of Dean Mining and Technical School and East Dean Grammar School—The Secretary, County Education Office, Shire Hall, Gloucester.

EDUCATIONAL RECONSTRUCTION

GENERAL REVIEW

IN NATURE of July 31 we published an article bearing the above title, and arising immediately out of the White Paper which had been presented to Parliament by the President of the Board of Education. The article was in the main expository and explanatory, further comment being expressly reserved for a later date. On the present occasion we give a general account of the situation as seen after some months of discussion in the country, and in following issues we hope to discuss special aspects of the comprehensive contents of the White Paper.

For a comparable effort to deal with education on a national scale, we have to go back to the year 1870, when W. E. Forster took the lead in the passing of the first Elementary Education Act. His declared object was to complete the existing voluntary system and to "fill up the gaps". His Bill was well received, but second thoughts on the part of his own political associates proved disastrous. As one turns over the pages of Hansard, one marvels at the melancholy tale of denominational jealousies and suspicions, and even though the lapse of seven decades has softened asperities, one is impressed with the wisdom of Mr. Butler's patient and cautious method of approach. The stern warning was repeated in 1902, when Balfour's measure established rate-aid for voluntary schools and along with it the dual system of control—opposed with all the bitterness of 1870, and still, as the White Paper shows, the chief stumbling-block in the path of the reformer. The other outstanding measure, that of 1918, conceived in a very different atmosphere, and at first supported with enthusiasm, remains to this day in great part a dead letter, as regards its socially significant provisions, namely, those relating to youth and to nursery schools. No wonder that, with this premonitory instance plain to be seen, the "exceeding lack of speed" in the proposals of the White Paper should have alarmed many of the firmest friends of education. They quite agree with the White Paper that laws cannot do everything, that laws "cannot build better human beings", and that "it is not the machinery of education so much as its content that will count in the future" ; but they remember also that the law's delays can do an infinite deal of harm. There is little doubt that we shall hear more of this when the Education Bill comes before Parliament.

From the broadly national point of view taken in this article, the most far-reaching statement in the White Paper appears unobtrusively and almost incidentally in paragraph 27 : "The key-note of the new system will be that the child is the centre of education and that, so far as is humanly possible, all children shall receive the type of education for which they are best adapted". The child the centre of education ! Of course no originality is claimed for this declaration. That the child is the true and only centre of education has for centuries been the merest commonplace in the best educational thought. Nor can it be claimed that it now appears for the first time in an official document, for it was the key-note also of Morant's famous introduction to the Code of 1904. Through his instrumentality, the child, not the official nor the tax-payer, nor even the teacher, was for the first time envisaged as the central figure in the educational scene, for whom, and for whom alone, that scene exists. The late Sir John Adams used to say that you had to hammer away for at least fifty years to secure a reform before anyone even began to listen; and was it not the late Lord Balfour who said that democracy must be led, not driven, but that it takes a lot of leading? When, however, democracy has made up its mind, the thing is done, and done far better than as the result of an autocratic decree. Let us hope that on this point our democracy has at last made up its mind.

Most of what follows will be in the nature of corollaries to this basic proposition. Large classes, for example, are condemned on the fundamental ground that they are bad for the child. "No teacher, however competent, can see to the development of an individual child's innate potentialities, or foster in it a healthy development of mind, body and character, if she has to deal single-handed with a class of 50 small children. This is not education but mass production" (par. 16). Large classes are always and necessarily bad for the child, though not obviously so for the teacher. For there is a type of teacher who can quite as easily manage fifty children as a dozen, and may indeed be happier with the fifty. But though he may please a superficially observant inspector or other visitor, he is not a good type of teacher, for the simple reason that he is satisfied with mass production. Large classes make it impossible for *any* teacher to meet the needs of the individual child—and that settles the matter.

The formula seven-to-eleven as the period to be spent in the junior school may commend itself to a person who surveys the educational scene from an office window. But it is in reality nothing but an administrative convenience. No scientific student of child nature, and indeed no close observer whatever, could approve of such a denial of the fact of individuality. Furthermore, the institution of an examinational test at the age of ten or eleven has had disastrous effects upon the aims and methods of the junior school, especially where competition for admission to secondary schools has been keen. Again, the White Paper takes the child's point of view, not that of the administrative machine—and the competitive examination goes. So also does the absurd assumption that any child's future development can by any imaginable means be safely foretold at the age of ten or eleven.

We have not observed that the proposed abolition of the examination at or before the age of eleven has called forth any lamentations. That is not quite true of the Norwood Committee's recommendation that the purely external examination for the school certificate should, "in the interest of the individual child and of the increased freedom and responsibility of the teaching profession", be gradually modified out of existence. Nothing could in point of fairness be better than the Committee's statement of the *pros* and *cons*, but its verdict is emphatic. Much of the opposition seems to have come from the men teachers, who are commendably anxious for the reputation of the certificate. The arguments employed are strongly reminiscent of the controversy which led to the present position in the University of London. Those arguments have in them a flavour of the nineteenth century, when the external examiner held universal sway, from the lowest to the highest of educational institutions. Let it be noted that the Committee's recommendation is in perfect accord with the White Paper. It is based upon "the interest of the individual child". The addition "and the increased freedom and responsibility of the teaching profession" is at bottom only another way of saying the same thing.

Coming now to the inevitable "religious difficulty", we note that in some quarters disappointment is expressed that the dual system of control is to be allowed to survive. For ourselves, we strongly suspect that if the matter could be left to the teachers and parents there would soon be an end of the difficulty. But we recognize that the whole history of our educational past is against that solution, and we can no more get away from that past than a man can get away from his own shadow. We are therefore left to admire the tact and patience with which Mr. Butler has handled his thorniest problem, and to express the hope that the intransigents, both of the Left and of the Right, may on this occasion sing small—again for the sake of the children of England. We observe also that many teachers are not so sure of the agreed syllabus being a sovereign remedy as the White Paper appears to assume. They reasonably point to the Board of Education's practice of issuing *suggestions* on the teaching of various subjects, a practice which is highly valued by the teachers, and they say that if an agreed syllabus is put forward as a suggestion rather than a mandate it would also be welcome. We are inclined to think that that is precisely the way in which an agreed syllabus will be viewed and utilized by a thoughtful teacher, who will reserve to himself a certain liberty of interpretation. The teacher may, we think, safely accept the agreed syllabus as representing at any rate "the next step".

The new system, the child-centred system, of which the White Paper speaks, falls into three stages—primary, secondary, and further education. To begin at the beginning, the nursery-school movement is excellent so far as it now goes. It is the outcome of the wisdom and enthusiasm of such persons as the McMillan sisters. The quality is there, but as to the quantity, nearly everything remains to be done, and there is no social problem more urgent. The proper aims of the primary school are well set forth in the Paper, but we are faced with the fact that even in places where re-organization has been arranged, the primaries are too often housed in buildings that make those aims impossible to realize. As for the secondary stage, the grammar schools, of course, we have with us, with their good record of achievement during the past twenty years, predominantly on academic lines. That those lines now need radical revision is strongly urged by critics who are by no means lacking in respect for tradition. They value the Norwood Report for its enunciation of principles, but contend that those principles are not carried to their logical conclusion in the recommendations as to curricula. Preparation for post-war citizenship calls, as we have said, for radical revision, but the Norwood Report tacitly asserts that the old bottles are safe containers of the new wine. This will never do. As for the modern schools, the White Paper waxes almost lyrical in describing their possibilities, and it is well to have the ideal set forth in an official document which has secured general approval. But the drab reality is that in respect of buildings, equipment, staff and 'amenities' nearly everything remains to be done.

We recite these examples, to which others may be added in subsequent articles, not indeed as a counsel of despair, but rather as an explanation of the deep concern expressed by educationists at the "excessive lack of speed" which the White Paper seems to view with complacency. Seeing that, for example, the intended raising of the leaving age and the progressive reduction of large classes depend upon the supply and training of teachers, the Board should take immediate steps, whatever the findings of the McNair Committee may turn out to be. The postponement of the reform of the dual system is held by experienced administrators to be quite unjustified by the facts. The omission of adult education from the first four-year plan is held to be unnecessary, seeing that much of it does not involve great outlay upon buildings and equipment. Finally, the case for forging straight ahead in the provision of nursery schools is, having regard to their social value both now and hereafter, quite unanswerable.

There are other problems arising out of the Paper which are not so urgent, but which are scarcely likely to be forgotten in parliamentary debates on the Bill. The reference to "public schools and other analogous schools" (paragraph 8) is one of them. In any discussion of the English public schools it is hard to disentangle reason and sentiment. However, two facts stand out clearly: (1) they have no counterparts in any other democratic country, and (2) though they are so few among so many, yet about three out of four of all the high offices of State and Church are filled by their products. Defenders of the public schools aver that if the schools produce leaders it is because of their intrinsic merits and nothing else. At this point the arguments begin to sway to and fro. If it be said that the basis of public school education is Christian, proof is demanded that the public school product is more markedly Christian than the county school product. If the defender of the public school says that it is independent of any other authority, he is asked whether standing aloof from the national system is really claimed as a merit. If he says that the headmaster has the power of what the Americans call 'hiring and firing', he is asked whether that is the kind of authority which should be vested in any one person. If he asserts that the child belongs to the parents and not to the State, and that parents have the right, by payment of fees, to choice and voice in their children's education, he is asked whether the parents who cannot pay fees thereby resign their rights to the State. And so the arguments succeed one another in a sort of ding-dong iteration. Probably the intelligent man-in-the-street, now that the full light of day is being cast on the situation, will find it hard to believe that the arguments produced are sufficient to explain the facts with which we started. Let us always remember, too, that most of the men and many of the women who will have to decide such issues are now scattered all over the world, and that post-war England may make short work of some of our hitherto accepted and uncriticized traditions.

Such are some of our second thoughts on the White Paper. The parliamentary discussion of its contents was interesting, appreciative and, on the whole, only mildly critical. When the Education Bill appears, the second thoughts of our legislators will resound through the land. It is to be hoped that both in its passage through Parliament, and in its subsequent translation into administrative action, it will fare better than its predecessors of 1870, 1902, and 1918.

MICE AND MEN

Voles, Mice and Lemmings

Problems in Population Dynamics. By Charles Elton. Pp. vii+496. (Oxford: Clarendon Press; London: Oxford University Press, 1942.) 30*s*. net.

In his preface, Dr. Elton tells us that: "The materials of this book have been assembled slowly for sixteen years. . . . The first part is a panorama of vole and mouse plagues in those countries for which records are available. The second part describes the vole and mouse fluctuations that occur in Great Britain and Scandinavia, and the methods developed at Oxford for the study of population dynamics in the field and laboratory. The third and fourth parts contain the history of similar fluctuations in Northern Labrador and Ungava that have an important influence upon the fur trade and the life of the natives." It may be said at once that the book is a great magazine of facts, a witness to the vast amount of useful work that has already been accomplished by Dr. Elton and his colleagues in the Bureau of Animal Population at Oxford, and it is enlivened by many a bright flash from the author. Nevertheless, it is not an easy book to review. The first two parts are excellent. But the reviewer feels, after reading them with great attention, that Parts 3 and 4 want pulling together; it would be worth while coaxing Dr. Elton later on, when he has forgotten the details and the archives of the Hudson's Bay Company and the Moravian missions, to write a little essay on this part of his subject.

Part 1, "Vole and Mouse Plagues", contains six chapters, of which the first, entitled "Ancient History and a Prophecy", is very fine. It opens with an account of Gérard's description of field-mouse plagues in Alsace during the six hundred years between 1271 and 1861 and directs attention to the immense literature of the subject. Dr. Elton says: "To comprehend the history of European mouse plagues one has to read, among other and less peculiar works, a fauna of Alsace by a French notary [Gérard]; a vole plague report by a learned Indian civil servant and oriental scholar [Elliott] who retired to become a landowner in Scotland; a folk-lore essay written by a classical scholar and head of an Oxford college [Powell]; a painstaking collection of classical references about animals by a school-teacher in Germany [Lenz]; and part of the works of Aristotle"—together with the Vulgate and English Bible cited by the author in his next paragraph. He says: "In spite of sweeping changes in God and circumstances, Authority has for several thousand years continued to act in much the same way, even to the present day. The Bible story is, if you like, a parable. The affair runs always along a similar course. Voles multiply. Destruction reigns. There is dismay, followed by outcry, and demands to Authority. Authority remembers its experts or appoints some; they ought to know. The experts advise a Cure. The Cure can be almost anything: golden mice, holy water from Mecca, a Government Commission, a culture of bacteria, poison, prayers denunciatory or tactful, a new god, a trap, a Pied Piper. The Cures have only one thing in common: with a little patience *they always work*. They have never been known entirely to fail. Likewise they have never been known to prevent the next outbreak. For the cycle of abundance and scarcity has a rhythm of its own, and the Cures are applied just when the plague of voles is going to abate through its own loss of momentum". In passing we may note that drastic cures sometimes prolong the ill; some years ago a group of tiny but valuable islands, in a Scottish loch, were devastated by water-voles, which resisted attack by keepers, dogs, traps and poison for many months. At last an expert, too lazy to need naming, was consulted; observing (to his relief) that the voles, for all their sleek appearance, were just living bags of pus, he fearlessly told the owner to close the islands and let the plague rip. The advice was taken and in a short time the voles disappeared, the grass grew again and the islands once more became good grazing.

In the remaining five chapters of Part 1 Dr. Elton reviews the history of vole and mouse plague in France, Germany, Holland, Italy, the Balkans, Russia, Palestine, Australia, the United States and Canada. He describes the efforts made by Pasteur, Loeffler, Danysz, and others to control the pests by bacteriological methods, and he gives a valuable account of Russian experience and research. He also develops the theme that the chief biological interest of "mouse-plague" centres in the periodicity of the fluctuations in the rodent population, and dealing with work done in the United States directs attention to the researches of Hamilton, who asserted that "it was possible to forecast high populations of mice 18 months before their appearance, while the mouse population was far from numerous. Following extensive warnings and suggested field practices 1½ years prior to the outbreak, orchardists were able to safeguard their trees in part from the most severe mouse infestation New York has ever experienced."

In Part 2 (pp. 126–233) Dr. Elton deals with the fluctuations in north-west Europe. He opens (Chapter 7) with a fine account of the Scottish vole-plagues of 1875–76 and 1891–92, which were remarkable not only for their severity but also for their location on the hills used for sheep-grazing. Sheep create conditions which are not favourable to undue increases in the vole population; whereas forest planting, for a time, favours the voles, grass growing luxuriantly in the plantations and affording abundant cover and food. We would remark in passing that voles, particularly species of Microtus, of which one was the species chiefly concerned in these plagues, are creatures of the open country and not of the forests; although they find convenient stations for recuperation at the edges of woods and in young plantations, sooner or later, when their numbers rise to a peak, they must swarm out into the open ground—sheep or no sheep. Winding up his account of these plagues and what was done to control them, Dr. Elton says: "In the impressive march of this outbreak we have seen a common but not extremely abundant inhabitant of the south Scottish hills increase suddenly within a year or two up to the absolute limit of subsistence, partially eliminating its chief competitor (the sheep), attracting to the area and maintaining for a short while a cloud of predatory birds, and giving also a feast for ground predators. Then its population subsides and leaves the predators in turn without subsistence. The grass recovers quickly and gives one of the best crops the shepherds have known."

In Chapters 8 and 9 an account is given of British research on the population dynamics of voles and mice between 1923 and 1939, that is of the work done by Dr. Elton and his associates in the Bureau of Animal Population at Oxford. Collett's account of the Norwegian lemming and its migrations and some of the fur returns of the Hudson's Bay Company cited by Gordon Hewitt were the sources from which Elton first gained the impression that rodent populations are subject to periodical fluctuations which occur quite independently of any variations (sometimes large) resulting from human interference. Later he found that this idea had been propounded, with characteristic insight, by Herbert Spencer in his "First Principles" so far back as 1863. It became the work of the Bureau to devise and to apply means and methods of testing this idea both in the study and in the field. The vast literature and the records of the Hudson's Bay Company and those of the Moravian missions were ransacked; field observations, including attempts to take at intervals a census of rodents and studies of their enemies in as many parts of the country as possible, were instituted on a large scale; and a long course of breeding and feeding experiments, together with a good deal of pathological and bacteriological research, was undertaken at Oxford.

In these ways much has been done already at the Bureau of Animal Population; but a great deal more remains to do. The problems involved have shown themselves to be subtle and of a far-reaching importance, which will tend to increase as the exploitation of 'backward' countries advances. Any detached philosopher, capable of taking one of those broad views in depth so cordially detested by statesmen and traders in all countries, will have little difficulty, after perusing this book and Lankester's "Kingdom of Man", in concluding that a world-wide biological service is one of the world's greatest needs, current disturbances notwithstanding. Such a service needs not only the co-operation of ecologists, systematists, and other scientific workers in all countries, but also public support. That can only be obtained from an educated public; and this education can best be given to the public by the museums, menageries and botanic gardens of the world. In all these institutions, to a degree varying with the character of each, attempts to bring the living world before the common man, to show the close interrelations of the fauna with the flora and of all their elements with one another, should be made by means of special exhibitions, lectures and publications. It is no longer enough to show the bare bones of systematics.

Meanwhile it is depressing to read of Dr. Elton's struggles to obtain financial support for the Bureau (p. 160). Participation in its work "usually involved a high personal risk to the continued livelihood of some or all of the members", leading naturally to undesirably frequent changes of personnel. "The search for money entailed a fantastic waste of energy and has slowly developed a skill in negotiations which can bear only an accidental relation to the real scientific value of a particular project." It is surely unworthy of a great country, with such vast interests in world agriculture, commerce, development, and the public health, to allow the Bureau to depend upon begging for its existence. So long as it does such work as is described in the present book, it will merit support from the State. The interest of the University of Oxford in the work of the Bureau is naturally more limited. Appeals to the world of commerce have been not unsuccessful; but commercial men are apt to have their own pet problems for solution and financial help from them too often deflects the man of science from his true goal.

Chapter 10 deals with Scandinavian lemmings and completes Part 2. Parts 3 and 4 are devoted to the periodical fluctuations in foxes, mice and lemmings, caribou and related creatures, including man, in Labrador and Ungava. Based largely on the records of the Hudson's Bay Company and the Moravian missions, they contain much hitherto unpublished material concerning Eskimos, Red Indians, and Whites in those countries as well as the great store of zoological information which is their chief purpose.

It remains only to note that the book is very well produced and illustrated with a frontispiece, showing an eighteenth century trapper, Captain George Cartwright, visiting his traps in Labrador, and with a number of clear maps and graphs.

M. A. C. HINTON.

LOGICAL EMPIRICISM

Between Physics and Philosophy

By Philipp Frank. Pp. v+238. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1941.) 15*s*. 6*d*. net.

THE title of this book is unfortunately chosen and is definitely at variance with the italicized statement on p. 103 that "*there are no boundaries between science and philosophy*". The suggestion of a sort of no-man's-land between physics and philosophy is indeed quite out of harmony with the ideas which Prof. Frank advocates. He was one of the original members of the "Vienna Circle" of logical positivists (or, as they have later been much better called, "logical empiricists"), and his book is particularly valuable for the authoritative account it gives of the origin and development of this school and its relations with cognate movements such as American pragmatism and the new logic of Russell and Wittgenstein. The book consists of reprinted addresses and articles extending over the period 1908–38, to which is prefixed a short historical introduction. It is clearly written, and should be read by all who are interested in the philosophical aspects of modern physics.

The main ideas of logical empiricism are now fairly well known in Great Britain, though it may be doubted whether their implications are widely understood. Perhaps the most concise statement of the most essential element of the system is given in the quotation from Carnap on p. 88: "There are no questions the answers to which are impossible for science in principle"—supplemented by the remark of Wittgenstein which follows: "When an answer cannot be expressed, neither can the question be expressed". Wittgenstein thus makes perfectly general what Carnap in this place restricts to science. Contrast with this the conjecture of Sir James Jeans that the "inner nature" of things (for example, of a centimetre) presents an essentially insoluble problem. Superficially it would seem as though Jeans had expressed an unanswerable question, but the logical empiricists would show (and here anyone who accepts the fundamental principles of science must acknowledge that they have proved their case) that he had merely written a succession of words without meaning. Obviously, to support their contention they must therefore pay special attention to the structure and function of language, and accordingly the more recent developments have been mainly in this direction. Carnap and Neurath in particular have directed investigations along these lines.

Without an appreciation of the way in which the logical empiricists have been forced to study language (and perhaps even with it) one can scarcely avoid the conclusion that they have allowed themselves to be diverted from the highway of progress in philosophy, along which they began to march, into a profitless *cul de sac*. Take, for example, the statement of the uncertainty principle (pp. 205–6). "Quantum physics says only that with certain experimental arrangements concepts like 'particle with a definite position' or 'particle with a definite velocity' can be defined. In other words, the physical processes which occur with these experimental arrangements can be predicted through statements in which one refers to 'a particle with a definite position' or 'a particle with a definite velocity', but there is no arrangement for which one can predict processes through statements involving 'a particle with a definite position *and* velocity'. This, however, does *not* mean that there are such particles, which, because of the defectiveness of our apparatus or because of malicious natural laws, we cannot measure in all their characteristics (position and velocity); it means rather that such combinations of words as 'a particle with coördinates x, y, z, and velocity v_x, v_y, v_z', must not be introduced into the language of physics". This is all very well, but why, in a free country, cannot we introduce such combinations of words if we wish? The answer in the end comes down simply to this, that we should then be led to expect experimental results (experiences) which do not occur. The language is therefore controlled by experience, and while it is, of course, essential that it should be so controlled, the insistence on a "physicalistic" as contrasted with a "phenomenalistic" language, in the interests of the unification of all science in a common language, seems to offer an easy passage to the control of experience by language.

The unification of science indeed comes perilously near to being enthroned as a dogma instead of being pursued as an ideal. It is the aim of every man of science to include more and more experience, of every kind, in a common logical system, but he is no true man of science if he does not recognize, first, that he may be aiming at the impossible, and secondly, that he is most likely to succeed in his object if he starts with different groups of experiences and correlates them by independent concepts, using independent languages, until by the growth of knowledge they may be united into a common system. Heat and mechanics began as independent studies, speaking independent languages, and later grew into the science of thermodynamics, for which the single language of energetics is sufficient. If the concepts and terms of the caloric theory had been denied to Carnot, what would have been the state of this science now ? Magnetism and electricity, radiant heat and light, chemistry and spectroscopy—examples are legion—all tell the same story ; and if, as we may hope, physics, biology and psychology are potentially one science, there would be little chance of their being recognized as such if the behaviourists, armed with the dogma of the logical empiricists' "physicalistic language", succeeded in depriving the infant science of psychology of all terms and concepts which physics at present does not need.

Prof. Frank devotes some attention to the social aspects of science, dealing in particular with the relation of logical empiricism to dialectical materialism. Here he is less convincing than in the more fundamental sections of the book. He introduces some special pleading in order to establish a likeness between the two systems of thought, and is accordingly forced to ignore the most essential elements of dialectical materialism. For example, he finds (p. 149) Lenin's doctrine that propositions such as "Matter is infinitely divisible" "are never to be labeled as true or false ; they are to be judged by their practical consequences" to be "very closely related" to the logical empiricists' view that "the truth of a proposition can only be judged if the methods of testing it are given". He omits to mention, however, that the "methods of testing" are utterly incompatible in the two cases, although two pages earlier he has stated that dialectical materialism "understands by test, above all, the test of a principle in social life, in revolutionary practice, as they put it". Does logical empiricism find the meaning of infinite divisibility in revolutionary practice ? Again, on p. 125 it is stated that a recent tendency to find support in modern physics for philosophical idealism has "no connection with any 'crises in physics' or with any 'new physical conception of nature'. It is rather associated with a crisis in human society arising from quite different processes". This is a remarkable statement from one who holds that the truth of a proposition can only be judged if the methods of testing it are given. By what test has Prof. Frank found a connexion between Jeans's 'mathematical God', which is particularly mentioned, and a "crisis in human society" ? And how has he established that the conception of that God has no connexion, not even an illogical one, with the quantum theory ? It is to be feared that here Prof. Frank is neither logical nor empirical ; he has used combinations of words which must not be introduced into the physicalistic language.

This, however, is a minor aspect of a book which, in the main, may be received with praise and gratitude. It is characteristic of the logical empiricists that (except in the later developments of their language analysis, which reveal everything about language except that it is intended to mean something) they express themselves clearly, unambiguously and, for the most part, convincingly. Prof. Frank has retained these qualities for thirty-five years. Let us hope that he will continue to interpret the development of one of the most significant of modern schools of philosophy.

HERBERT DINGLE.

SCIENCE AND INDUSTRY OF PLASTICS

Synthetic Resins and Allied Plastics

By Various Authors. Edited by Dr. R. S. Morrell. Second edition. Pp. xiii+580. (London: Oxford University Press, 1943.) 35*s*. net.

THE second edition of "Synthetic Resins and Allied Plastics", edited by R. S. Morrell, reflects the spectacular advances made in this field of applied chemistry, inasmuch as ten experts have been called on to collaborate in the production of the present volume. It is only five years ago since the first edition, compiled by four authors, made its appearance, endeavouring in one volume to cover the whole of the plastics industry from both technical and theoretical points of view. The present edition is structurally similar to the first edition, but considerably expanded to cover the progress made during the past five years. Each chapter is a condensed review of individual fields of plastics.

For the ordinary reader the introductory chapter is almost, in itself, a sufficient review of the industry and science of plastics, but the succeeding chapters on resins derived from proteins, cellulose, phenols, and urea in combination with formaldehyde, on the vinyl, acrylic and coumarone polymers, the ester gums, and finally on the alkyd and petroleum hydrocarbon resins, are exhaustive in their detail, and possibly only those intimately connected with this branch of applied science can thoroughly appreciate the vast strides made in recent years.

There are also special sections on the application of phenol and urea-formaldehyde resins as components of varnishes and enamels, and a very interesting chapter on miscellaneous resins wherein are described many plastics which command attention either on account of their mode of formation or because of their specialized application, but which have not yet been sufficiently developed to justify classification into groups. Included in this edition also are chapters on electrical tests carried out on resins and on methods of identification of resins. This latter, together with two sections on the theory of resinification, will give much food for thought and should be productive of new ideas and methods of approach in the elucidation of this problem. Finally, there are many illustrations, and each chapter is amply supported by a very comprehensive list of references to original publications.

This brief summary of the contents of the work will serve to show the wide field of readers to whom this valuable book should appeal. Not only the technician but also the more secluded research worker will find a very full account of the progress of the science of plastics, and also much theoretical information. Undoubtedly this edition will be eagerly sought after by all those interested in the science or engaged in the manufacture of modern plastics.

The Technique of Radio Design

By Dr. E. E. Zepler. Pp. xii+311. (London: Chapman and Hall, Ltd., 1943.) 21*s*. net.

The author of this book has had a number of years experience as a radio designer in the research and development departments of two well-known commercial firms, one in Great Britain and one in Germany; and the book records much of that experience as an aid to the radio equipment engineer in dealing with his daily routine problems.

The scope of the work covers the design and basic construction of radio communication receivers of all types, and concerns intimate details of receiver work rather than a comprehensive treatment of principles, which are already adequately catered for in other publications. The first chapter, on "Some Fundamental Theoretical Facts", is preceded by a list of symbols and some useful formulæ and graphs on the inductance, capacitance and impedance of wires, coils and feeders. The succeeding chapters then deal in a very practical manner with the transfer of the received signal from the aerial to the first amplifying stage, and so on to the detection and frequency-changing portions of the receiver. The problems arising from the requirements of selectivity, gain and frequency control and the necessity of suppressing or limiting receiver noise, hum and spurious beats are described; and it is gratifying to find a whole and very practical chapter devoted to the important subject of screening in the various ways in which it is relevant to the design of a good radio receiver. Later chapters deal with power supply, routine measurements and fault finding.

The book is to be recommended as a good combination of theory and practice, and should be at the disposal of all engineers and physicists concerned with the design of radio-receiving equipment, whether of an experimental or commercial type.

Food and Farming in Post-War Europe

By P. Lamartine Yates and D. Warriner. (The World To-day Series.) Pp. 118. (London, New York and Toronto: Oxford University Press, 1943.) 3*s*. 6*d*. net.

The reconstruction of European agriculture will be one of the most urgent and complex tasks confronting the United Nations on the conclusion of hostilities. It is not reconstruction so much as revolution that is required to dispel the grinding, hopeless poverty of the vast mass of peasantry that has been a chronic cause of economic and political unrest, particularly in south-eastern Europe. For the sake of brevity the authors of this book have simplified the presentation of the problem without, however, sacrificing clarity. There are far too many farmers in Europe, they produce the wrong kinds of foodstuffs, they are ill-fed, and they are unorganized economically. The basis of re-organization must be increased industrialization to relieve rural over-population, the substitution of intensive mixed farming for predominantly grain farming, and great improvements in technical efficiency and marketing. The rural and urban populations would be economically complementary, each providing a steady market for the produce of the other. The economic, social and political obstacles to the realization of such a plan are immense, and the authors confront them boldly. They are, however, confident that they can be overcome, and their arguments, supported by well-marshalled facts, lend support to their confidence.

Land, Air and Ocean

By R. P. Beckinsale. Pp. 407+18 plates. (London: Gerald Duckworth and Co., Ltd., 1943.) 15*s*. net.

To compress into a single small volume an account of all aspects of the physical basis of geography is an ambitious task, but on the whole the author has been successful. It may be questioned whether the book is full enough for university work, but it certainly touches on nearly all problems that have to be considered and gives, on each chapter, useful and modern references for further study. There are even indications of the human bearing of the physical considerations. Naturally some parts are fuller than others. The chapters on the atmosphere are perhaps the best and include mention of much recent work. Some revision and amplification would not be out of place in the account of ocean waters and submarine relief, and in the paragraphs on icefields. On many subjects it is difficult to compile a short but comprehensive list of further reading, but a few additions would not be out of place in the chapters mentioned. There are several well-chosen diagrams and photographs. The book, though condensed, is most readable.

Tables of Legendre Associated Functions

By Zaki Mursi. (Fouad I University: Faculty of Science, Publication No. 4.) Pp. viii+286. (Cairo: Fouad I University, 1941.)

Until recently the only tables of the associated Legendre functions $P_n^m(x)$ were those of Tallqwist (Helsingfors, 1906), who calculated them for values of n and m up to 8 and for values of x from 0·00 to 1·00. As the function vanishes when the positive integer n is less than the positive integer m, Tallqwist's tables contained 3,600 entries. He calculated functions of even order exactly, and those of odd order with an accuracy varying from four to ten decimal places. Now the Fouad I University at Cairo has provided a much more extensive table, for values of n and m up to 10, and for values of x from 0·000 to 1·000. The entries have been obtained correct to 8 decimal places, except for $n = 9$, 10 and m equal to or greater than 5, where, as the entries are large, the values have been calculated to four decimal places only. Parts of the tables have been checked by Dr. L. J. Comrie, whose knowledge and experience of mathematical tables are exceptionally wide.

The Biological Control of Insects

By Hugh Nicol. (Pelican Books, A.113.) Pp. 174+8 plates. (Harmondsworth and New York: Penguin Books, Ltd., 1943.) 9*d*. net.

The control of insect pests by means of parasites and predators appeals to the biologist and the general public alike. The biologist sees in the method the practical application of scientific knowledge by the utilization of living organisms. To the public it forms an attractive chapter in the progress of applied science. Dr. Nicol has recounted the history and practice of the methods of biological control in an attractively written volume. His account is accurate, free from undue technicality and shows an unbiased detached viewpoint. It can be recommended to a wide circle of readers including scientific folk themselves. As the author remarks, there is science, and also material for philosophy, for the reader who looks a little beneath the surface of the story, here recounted, towards the deeper issues.

PRINCIPLES OF INSECTICIDAL BIO-ASSAY

By DR. H. HURST

Department of Colloid Science, Cambridge, and Imperial College of Science and Technology, London

THE need for standardized methods of testing insecticides has become an important factor in insecticidal research, especially where routine examination of new materials is desirable. Chemical assay may provide an index of the potential toxicity of an insecticide, but evidence has been provided recently to show that the influence of toxicant concentration in an insecticide may be completely obscured by variation in the physico-chemical properties of the carrier medium[1]. The fact that each component of an insecticide may contribute towards gross toxicity restricts the usefulness of chemical assay as an index of toxicity. Hitherto, attempts which have been made to correlate chemical and biological tests have been based on the invalid assumption that the main purpose of a carrier medium is to transmit the insecticide to the test insects, after which toxicant concentration is a limiting factor in biological activity. This assumption has provided a general basis for 'standard' methods of insecticidal bio-assay, in which attention has been directed more towards arbitrary elimination of unknown variable factors than towards the fundamental causes of this variation[2].

In the present article an attempt is made to analyse some of the main factors which influence dosage-biological activity relations in systems in which insecticides are brought into contact with insects under controlled conditions.

The fundamental variables in an insecticidal test system may be resolved into (1) the test insect, (2) the insecticide, and (3) the mode of application of the insecticide to the test insect.

The choice of test insect is of prime importance in the design of the particular test system, for when the insecticide and mode of application remain constant, insecticidal evaluation depends on the sensitivity and specific susceptibility of the test insect.

An insecticide generally consists of a toxic principle or toxicant which is dissolved or otherwise dispersed in a carrier medium, which may be a homogeneous liquid or a heterogeneous system of mixed components. The potency of the insecticide is then evaluated from dosage-biological activity relations, where 'dosage' refers to the application of a standard quantity of insecticide, and 'biological activity' is measured by some selected specific response shown by the test insect.

The biological activity of an insecticide may vary greatly according to the mode of application used. In practice, liquid insecticides are usually applied as an atomized spray, which may be used in the control of flying insects, or deposited as a 'film' on various surfaces for secondary transmission to insects which come into contact with these surfaces.

These considerations may be illustrated by some selected examples in which insecticides are applied to insects in systems which represent the limits of a range of conditions under which insecticides are generally used in practice.

System 1

Components.—Test insect; pure toxicant.

Mode of Application.—Complete immersion of test insect in pure toxicant.

The simplest method of external insecticide application consists in immersing the test insect in relatively large proportions of pure drug. Since the external drug phase is large in relation to the biological test system, the disturbing influences of drug depletion in the external phase and drug distribution between the carrier medium (which is normally present in insecticidal mixtures) are avoided. In practice, this type of system is rarely used, for it is important to measure insecticidal action over as wide a range of toxicant concentrations as possible. Moreover, very few insects will resist immersion in pure toxicant for a sufficient period of time to ensure accurate experimental observation of specific biological responses. Nevertheless, systems of this type are very useful for measuring the relative molecular reactivities of members of homologous series of drugs, since distribution between an external carrier phase and the biological system is not a limiting factor in drug access. Mature blowfly larvæ (*Calliphora erythrocephala*, *Phormia terrænovæ*, *Sarcophaga falculata*) are suitable test insects which are extremely resistant to high toxicant concentrations present as an external insecticidal phase.

Even in simple systems of this type, complex factors are involved in the production of specific biological responses such as paralysis, or death. For example, a drug may 'induce' its own penetration or access through the cuticle by interacting with the lipo-protein components of the cuticle framework. In other words, the resistance of an insect to an insecticide depends on 'functional cuticle permeability', which is determined by the nature of the drug-cuticle association in the particular test system[1].

It has generally been assumed that drug specificity depends mainly on the molecular interaction of the drug with the ultimate cell receptors at the site of action in the biological system. But where the drug has first to penetrate through an intermediary biophase which links the site of drug application with the site of drug interaction, the effects of molecular specificity may be completely obscured by diffusion processes involved in drug access. In fact, with insects such as blowfly larvæ, the relative toxicities of drugs such as normal primary alcohols and fatty acids measured by iso-active external concentrations differ markedly from relative drug reactivities based on iso-active internal concentrations in the hæmolymph.

The importance of this fundamental conclusion lies in the implication that where differences in permeability exist between the cuticles of a range of test insects, the relative biological activities of a range of drugs or insecticidal mixtures measured with one particular species of test insect will not necessarily be similar to corresponding 'evaluations' with other species of test insects. This factor is a difficulty which stresses the need for caution in the correlation of the results of insecticidal bio-assay in different test systems, and shows that physiological factors must also be considered in assessing the toxicity of insecticides.

System 2

Components.—Test insect; toxicant; carrier.

Mode of Application.—Complete immersion in insecticidal mixture.

Systems of this type may be classified broadly into three main categories in which biological activity depends on certain limiting factors.

A. Carrier non-toxic; toxicant non-toxic. Carrier

+ *toxicant non-toxic.* Mature larvæ of the blowfly *Sarcophaga falculata* will remain active for more than an hour when immersed in kerosene or ethyl alcohol; mixtures of ethyl alcohol and kerosene are also relatively non-toxic. The limiting factor is the impermeability of the insect cuticle; variation in the relative proportions of carrier and toxicant produces no significant change in biological response.

B. Carrier non-toxic; toxicant non-toxic. Carrier + toxicant toxic. (1) When immersed in pure kerosene or ethyl alcohol, mature *Calliphora erythrocephala* larvæ behave similarly to Sarcophaga larvæ, and show no symptoms of paralysis even after an hour. Mixtures of ethyl alcohol and kerosene are extremely toxic, and the insects are rapidly immobilized—within a few seconds. The functional permeability of the cuticle is so high in the presence of kerosene that rapid access of the ethyl alcohol to the internal body fluids of the insect results in an increase in volume of about 50 per cent within three minutes. This stage is followed by the bursting of the insect when the internal pressures become excessive. These effects are produced with great rapidity by mixtures containing 20–80 per cent alcohol. On either side of this range equitoxic effects may be produced, showing that *toxicant concentration* is not necessarily a limiting factor in biological activity when an external insecticidal mixture is brought into contact with an insect. Where the concentration of alcohol is low, toxicity will increase with increase in alcohol concentration, since within this range toxicant concentration is a limiting factor in drug access. But where the concentration of ethyl alcohol is high, toxicity will decrease with increase in toxicant concentration, since within this range functional cuticle permeability decreases with decrease in carrier activity.

(2) A similar example of more practical importance is shown by the influence of 'carrier activity' on the biological activity of pyrethrins, which show a higher degree of insecticidal activity than any other known natural or synthetic insecticide. Primary symptoms of pyrethrin intoxication are produced very slowly when mature Sarcophaga larvæ are immersed in a concentrated pyrethrum extract containing 30 per cent pyrethrins*, and the insects become immobilized within 20–30 minutes. In this system the carrier for pyrethrins consists of a mixture of fatty acids, resins, and other impurities derived from the original pyrethrum extract, and carrier activity is low. Dilutions of this concentrated extract with a heavy oil of the medicinal paraffin type show no marked change in biological activity until low toxicant concentrations are reached, when further dilution with heavy oil produces a decrease in biological activity.

(3) If the original concentrate is diluted with a lower boiling paraffin fraction of the kerosene range, carrier activity becomes very apparent at very low concentrations of kerosene (2–5 per cent), and as dilution proceeds there is a progressive increase in biological activity of the drug mixture. This is due to the rapid increase in functional cuticle permeability which is induced by the association of the kerosene with the cuticle framework[1]. Carrier activity is inversely proportional to carrier viscosity, and in this system functional cuticle permeability is so high that complete paralysis is produced within 1–2 minutes by solutions containing pyrethrin concentration so low as 0·005 per cent. Evaluation of toxicant activity is only practicable within a very restricted range owing to the rapidity of paralysis inception.

Systems (2) and (3) represent the outer limits of a range of test systems in which toxicant activity may be used as an index of carrier activity, since the rate of drug access is determined mainly by the functional cuticle permeability.

C. Carrier toxic; toxicant toxic. Carrier + toxicant toxic. Tenebrio molitor larvæ are immobilized within 1–2 minutes by immersion in kerosene, ethyl alcohol, or mixtures of these components. Owing to the relative susceptibility of the test insects under the particular mode of application of the insecticide, toxicant and carrier activities are masked by carrier toxicity. In systems *A* and *B*, carrier toxicity is small. Many flying and crawling insects (for example, adult Diptera, larval and adult stages of Coleoptera, Lepidoptera, nymphal and adult stages of Orthoptera, Hemiptera) are susceptible to carriers such as kerosene, and such test insects are unsuitable for test systems in which the external insecticidal phase is relatively large in relation to the test insect.

From these examples it is clear that, in a particular test system, the biological activity of an insecticide depends not only on the nature and concentration of the toxicant, but also on all other components of the insecticidal mixture, irrespective of the toxicity of these components, and that bio-assay gives a measure of a gross summation of effects which may be analysed by the appropriate choice of biological component. In systems where carrier toxicity is not a limiting factor in bio-assay (*B*, (1), (2), (3)), relatively enormous changes in biological activity of an insecticidal mixture containing a fixed proportion of toxicant may be produced simply by variation of the carrier components. The importance of physiological factors is shown by the contributory influence of carrier toxicity on the biological activity of an insecticidal mixture. Where the external insecticide phase is relatively large, carrier toxicity may completely swamp bio-assay of toxicant activity (*C*). Where low cuticle permeability is a limiting factor in drug access, bio-assay of toxicant activity is also impracticable (*A*).

System 3

Components.—Test insect; toxicant; carrier.

Mode of Application.—Insecticide applied to test insect by secondary transmission from residual 'film' primarily deposited on absorbent substrate.

The difficulties inherent in methods of assay where the carrier itself is toxic may be surmounted by the introduction of an additional limiting factor into systems of the above type. For example, the poison mixture may be first deposited on a porous substrate where a proportion of the mixture becomes immobilized by absorption or adsorption processes. The deposit of poison mixture in the porous surface may be adjusted to form a thin film on the surface of the framework. 'Film activity' may be measured by introducing suitable test insects on to impregnated substrates which comprise a range of deposit volumes and toxicant concentrations. The biological responses produced depend on (1) toxicant concentration and (2) film thickness, which influences the transmission of insecticide to the test insects, and also 'sensitizes' the insects to the action of the toxicant. Where the insects are susceptible to carrier toxicity, excessive film thickness produced by substrate satur tion deposits results in a system which approximates to system 2 *C*, and toxicant bio-assay is impracticable.

---

* The author is indebted to Dr. T. F. West (Messrs. Stafford Allen and Sons, Ltd., London) for preparing the pyrethrum extracts used in these experiments, and also for valuable technical advice.

By the selection of an appropriate range of film thicknesses, the disturbing influence of individual biological variation on the susceptibility of the test insects may be largely eliminated by superimposing on this individual variation a predetermined wider range in 'functional susceptibility'. Where film thickness is small, insect functional susceptibility is low, and toxicant bio-assay is possible at high initial toxicant concentrations. Similarly, with increase in film thickness, there is a decrease in the threshold active toxicant concentration in the bulk phase of the insecticidal film. In this way bio-assay of insecticidal activity may be carried out over a relatively wide range in toxicant concentrations. The sensitivity of this method is illustrated in the accompanying table by some typical data for the insecticidal film activity of pyrethrum – kerosene sprays to *Calandra granaria* weevils.

Analysis of results. In practice the biological activity of an insecticide represents a summation of the effects of toxicant activity, carrier activity, and carrier toxicity. Hence a representative index of biological activity is obtained by summation or average of the biological responses produced by a given initial toxicant concentration applied at dosages *A*, *B*, *C*, *D*, which comprise a comprehensive range of carrier activities and carrier toxicities.

Substrate: Whatman No. 1 Filter paper, 7 cm. diameter.
Dosage Deposits: *A*, 0·1 c.c. (0·0026 c.c./sq. cm.)
B, 0·12 c.c. (0·0031 c.c./sq. cm.)
C, 0·14 c.c. (0·0036 c.c./sq. cm.)
D, 0·16 c.c. (0·0042 c.c./sq. cm.)
Initial age of films, 20 min.
40 Calandra weevils per filter paper (exposed in open petri dishes, 25° C.; relative humidity, 70 per cent).

In the above system carrier toxicity becomes a limiting factor at substrate saturation deposits of approximately 0·3 c.c. per filter paper. The system approximates to system 2 *C*, and rapid immobilization of the test insects precludes bio-assay of toxicant activity. Dilution (0·05 per cent pyrethrins) may be conveniently used as a standard for comparison with a range of kerosene dilutions of pyrethrum-kerosene sprays of unknown pyrethrin content. Bio-assay is based on the ratio of average percentage paralysis per deposit range *A*–*D* to that of the standard. This ratio gives a coefficient, which may be expressed generally as the *I.C.T. Coefficient* (*I*, test insect; *C*, carrier; *T*, toxicant). In this way particular test systems may be specifically defined. For example, from the data summarized in the accompanying table the *I.C.T.* (*Calandra—kerosene—pyrethrins*) coefficients of film activity (3 hr.) of insecticides containing 0·06, 0·05 and 0·04 per cent pyrethrins, are 1·11, 1·00 and 0·86 respectively; corresponding values at twenty-four hours exposure are 1·10, 1·00 and 0·92 respectively. For this range, bio-assay of toxicant concentration is possible within wide limits of dosage exposures (3–24 hours); at higher toxicant concentration (0·06–0·10 per cent pyrethrins), bio-assay is obscured by excessive toxicant activity.

The insecticides are deposited uniformly on the filter papers by means of a graduated micro-pipette (total capacity 0·2 c.c.). With low-viscosity oils such as kerosene, diffusion equilibrium in the system insecticide – substrate is rapidly attained, and uniform sampling of the insecticidal film is brought about by the activity of the test insects. In practice, the number of standards used may be restricted to the range 0·04–0·06 per cent pyrethrins. The unknown insecticide is then diluted with standard kerosene spray base to give a range of insecticides which are approximately iso-active with those within the range of standards. The pyrethrin content of the unknown may then be assessed from the dilution factor. By the appropriate choice of standards and dosage deposits a wide range of pyrethrin contents may be assayed.

Bio-assay of pyrethrum heavy-oil preparations. The carrier activity of a heavy oil of the medicinal paraffin type (for example, Shell oil *P*.31) is small in relation to that of a carrier medium such as kerosene, and higher pyrethrin concentrations are necessary to produce comparable biological responses within a given period of exposure. A range of standards containing 2–0·2 per cent pyrethrins may be used for preliminary 'sorting out' tests. Sensitivity within this range is greatest in the region of 1 per cent pyrethrins. For example, the *I.C.T.* (*Calandra* – *P*.31 – *pyrethrins*) coefficients of solutions containing 1·2, 1·0 and 0·8 per cent pyrethrins are respectively 1·14, 1·00 and 0·59 (3 hr.); 1·09, 1·00, 0·76 (24 hr.).

Scope of Method. Measurement of *I.C.T.* coefficients at intervals gives an index of the nature of the intermediary chain of biological responses which culminates in eventual mortality. This is of importance where secondary toxicants or 'activators' may be present. In the system pyrethrins – kerosene – sesame oil, the kerosene is a *primary* activator for pyrethrins in so far as 'knock-down action' or paralysis is determined by the increase in functional susceptibility of the test insects which is induced by the kerosene. Sesame oil is a *secondary* activator which does not increase 'knock-down action' (high sesame oil contents of 30–50 per cent *decrease* the knock-down activity of pyrethrum-kerosene sprays by inducing a selective decrease in functional cuticle permeability), but results in combined action with pyrethrins at a later stage when the recovery phase of pyrethrin poisoning normally occurs. The efficiency of a secondary activator for pyrethrins, such as sesame oil or *iso*butylundecylenamide, may be assessed from the minimum concentration of activator which eliminates the recovery phase of standard pyrethrum-kerosene solutions by the inception of secondary *irreversible* toxic action during this phase. Bio-assay of an insecticidal spray containing a secondary activator should be based on analysis of biological activity at various stages after spray application to the test insects. For example, under practical conditions, the 'knock-down' efficiency of a pyrethrin-oil spray for flying insects is influenced primarily by pyrethrin content and carrier activity of the oil medium; the secondary effect of activators such as sesame oil becomes apparent after this initial 'knock-down action'.

This method of assay, which involves the use of a range of dilutions of toxicant, has many features in common with the Rideal-Walker (R-W) test for the evaluation of the killing efficiency of disinfectants[3]. Here the weakest concentration of disinfectant killing standard bacterial cultures in a definite time period is divided by the weakest concentration of phenol killing in the same period; the ratio is the phenol coefficient. With a range of dilutions to cover threshold toxic concentrations, greater sensitivity is obtained than is possible using a reference standard at a single fixed concentration.

System 4

Components. Test insect (flying); toxicant; carrier in closed chamber.

Mode of Application. Insecticide introduced into chamber as atomized spray.

In Systems 1 and 2, where the external insecticidal phase is large in relation to the biological component, the capacity of the insecticide/cuticle interface for transmission of insecticide to the insect is at a maximum, and toxicant dosage is mainly determined by functional cuticle permeability and by the period of immersion in the insecticidal mixture, since carrier toxicity is not a limiting factor in bio-assay. In System 3, carrier toxicity may be eliminated as a dominant factor in biological activity by a controlled mode of application of insecticide in which the bulk of the insecticide is primarily immobilized in a porous substrate so that secondary transmission to the insect is determined by the *local* capacity for transmission of insecticide at the insecticidal film/cuticle interface. In Systems 1, 2 and 3 the relations of the insecticidal components and test insects are such that uniformity in the mode of application of insecticide to the test insects may be controlled so as to assess the relative influence on gross biological activity of toxicant activity, primary carrier activity, carrier toxicity, and secondary adjuvant or activator activity.

Where the test insects are flying insects enclosed in a spray chamber, and the insecticide is introduced as an atomized spray, individual insect dosage is largely dependent on the insect distribution and spray distribution relations. A system of this type is used in the Peet-Grady method, which is the official method of the National Association of Insecticide and Disinfectant Manufacturers for evaluating liquid insecticides[4]. Uniformity of experimental conditions is obtained by arbitrary standardization of unknown variables. The test procedure involves the use of a standard fly-rearing room, testing room, test chamber, fly cages, atomizer, and insecticide paper which is used to line the floor of the test chamber in which the flies are sprayed.

The dosage-biological activity relations in this method of test are extremely complex. For example, reduction of exposure time of 10–5 min. has been shown to have little influence on the knock-down and kill when a standard 12 ml. dosage is used[5]. An extension of these experiments by the present author has shown that an increase in exposure period from 5 to 120 minutes results in only a slight increase in toxicity. The kills obtained at exposure periods of 5, 10, 15, 20, 30, 60 and 120 minutes were 35, 36, 32, 34, 36, 43 and 49 per cent respectively*. It is interesting to note that despite a large variation in exposure period the relative biological activities of standard dosages sprayed into the chamber remain relatively constant. This indicates that toxicity is mainly determined by the initial dosage transmitted to the flying insects during and shortly after spraying, although with kerosene-type sprays a residual 'mist' of finely atomized spray droplets may persist for about twenty minutes. The reproducibility of the results obtained under these conditions cannot be attributed to uniformity in individual fly dosage. A threefold variation in average fly dosage has been demonstrated by a careful colorimetric analysis of the individual dosages received by flies sprayed with insecticides containing suitable dyes under standard Peet-Grady test conditions[6]. This evidence suggests that fly distribution is a dominant factor in individual fly dosage – biological activity relations, since the gross variation in individual fly dosage can scarcely be ascribed to lack of replication in the gross characteristics of spray distribution. The disturbing influence of spray distribution is shown by the fact that the relative toxicity of pyrethrum-oil insecticides may be completely reversed by variation in the sprayer used. Moreover, the present author has found that at spraying pressures of 2, 12·5 (normal), and 25 lb./sq. in., the kills produced by standard 12 c.c. dosage of *O.T.I.* (Official Test Insecticide, approximately equivalent to 0·1 per cent *W/V* pyrethrins in a kerosene spray base) were 15, 36 and 45 per cent respectively, showing that toxicity increases with spraying pressure*.

From this evidence the general conclusion may be drawn that in systems in which an insecticide is applied as a spray to flying insects confined within a closed chamber, uniformity of individual insect dosage is limited by dominant factors of fly distribution and spray distribution, which are characteristic of particular systems.

This fundamental conclusion has provided a basis for the investigation of the general dosage – biological activity relations in systems of this type. A detailed account of the numerous variable factors involved is beyond the scope of the present article, and will be given elsewhere, but the following brief summary will serve to illustrate the complexity of the factors which contribute towards gross toxicity.

(1) For a given test chamber and sprayer, bio-assay of toxicant activity may be completely obscured by variation in carrier activity. A standard dosage of a solution of 0·1 per cent pyrethrins in a heavy oil carrier (Shell oil *P*.31) produces only a slight knock-down action (30–50 per cent) during the standard exposure of ten minutes in a Peet-Grady chamber, and cannot be evaluated by comparison with a similar standard consisting of a 0·1 per cent solution of pyrethrins in kerosene where carrier activity is high[1].

(2) Where the toxicant has a relatively high vapour pressure (for example, organic thiocyanites

---

* The author is indebted to the Shell Refining and Marketing Company, Technical Prods. Dept., London, for the use of a Standard Peet-Grady Chamber in which these tests were carried out.

such as 'lethane' or 'thanite'), toxicity depends on (1) contact activity of the toxicant carrier liquid phase, and (2) fumigant activity of the toxicant phase; (2) is relatively independent of (1).

Some rather 'aberrant' results may be obtained when spray chambers are used for the evaluation of insecticides in which different toxicants and carriers are present. For example, the toxicity of an insecticide consisting of a solution of pyrethrins in heavy oil *increases* on dilution with a kerosene spray base owing to an increase in carrier activity (*cf.* systems 2*B*, 2, 3). On the other hand, variation in carrier activity produces only a slight variation in toxicity of sprays containing lethane or thanite, since fumigant toxicant activity is an important factor in gross toxicity. In other words, for given initial toxicant concentrations the relative toxicities of pyrethrum–oil, lethane–oil, and thanite–oil sprays may vary within wide limits simply by appropriate 'adjustment' of carrier activity. Two per cent thanite–oil sprays which show a higher official Peet-Grady rating than *O.T.I.* show a considerably lower rating when tested by the *I.C.T.* coefficient rating (System 3), since fumigant activity is no longer a limiting factor in bio-assay.

(3) With decrease in chamber size, the disturbing influences of fly distribution and spray distribution factors on individual fly dosage diminishes, since it is possible to attain more uniform and higher initial spray concentrations than is practicable with larger chambers of the Peet-Grady type. This is shown by the relatively high initial rates of knock-down produced in the smaller chambers, especially where the toxicants used exert fumigant activity. Similar results have been obtained independently by other investigators[7].

(4) Where the spray storage capacity of the floor of the spray chamber is small, secondary transmission of insecticide from the floor of the chamber to the test insects may be an important factor in gross dosage-mortality relations, since the bulk of the spray is eventually deposited on the floor (*cf.* System 3). The adhesion of finely atomized oil spray droplets to vertical surfaces in the chamber is relatively small. Where the floor of the chamber is lined with an absorbent surface or substrate of high spray storage capacity, film activity is slight and toxicity is mainly influenced by initial spray administration and residual 'mist action'.

It is clear that the physico-chemical factors which influence the dosage–biological activity relations in fly spray chamber methods of insecticidal bio-assay are extremely complex and only become apparent after comparison with much simpler systems of the types 1, 2 and 3. Careful arbitrary standardization of unknown variable factors in the Peet-Grady method is of doubtful significance where variation in carrier activity may obscure variation in toxicant activity. In fact, the use of a standard reference insecticide such as *O.T.I.* as a basis for the evaluation of pyrethrin content in samples of unknown composition is only valid for a restricted range of insecticides in which carrier activity is of a similar order to that in the standard. Where the unknown samples contain toxicants other than pyrethrins, bio-assay provides an index of a gross summation of effects which are characteristic of the particular test chamber and do not necessarily hold in other chambers or under practical conditions of test where, for example, fumigant activity is negligible. Caution is also necessary in the correlation of the biological activity of a spray with some relatively simple factor such as particle size distribution, for kinetic factors are also involved in the transmission of the spray droplets to the insects. High viscosity oils, even when finely atomized, are ineffective under practical conditions owing to dispersion factors, and droplets of less than 17 microns seldom strike the object towards which they are sprayed[8].

It is hoped that the principles which have been illustrated in the present article may serve as a guide to other investigators in the field of insecticidal research, especially those who are primarily concerned with the bio-assay of insecticidal preparations of unknown composition and physico-chemical properties. It is only from the scientific analysis of the limiting factors which influence the biological activity of an insecticide in a selected range of controlled test conditions that the ultimate efficiency of the insecticide under more variable field conditions may be assessed with any degree of accuracy.

THE BIOLOGICAL SECTION OF THE UKRAINIAN ACADEMY OF SCIENCES

By NIKOLAI GRISHKO

AT the present time the Ukrainian biologists are working in the sister republic of Bashkiria, where the Ukrainian Academy of Sciences was evacuated from its home in Kiev.

The Institutes of the Academy are continuing their valuable research work on the development of theoretical subjects in various branches of biology, and at the same time have included in their programmes of work a number of practical problems connected with war surgery, therapy and general war medicine, and problems connected with the maximum utilization of the natural resources of the country and the increase in the output of agricultural products.

Several of the Institutes' laboratories are working on problems connected with the more rapid healing of wounds, the knitting of fractured bones, problems connected with relieving the sufferings of the wounded and ensuring their more rapid return to the ranks.

Prof. A. Bogomolets, director of the Institute of Clinical Physiology, has proved that the employment of the anti-reticular cytotoxic serum is very effective in speeding up the processes of healing flesh and knitting broken bones.

This new treatment is already widely used in the hospitals and clinics of the Soviet Union. It is one of the results of many years research by Prof. Bogomolets and his pupils into the part played by connecting tissues in the organism, research work which is being successfully continued to-day.

Prof. Nina Medvedova, one of Prof. Bogomolets' colleagues, has discovered new functions of the cortex of the suprarenal glands—functions which regulate carbohydrate metabolism. She has succeeded in producing, in the form of an extract, the hormone of the cortex of these glands, which she has named 'corticalin'. Corticalin is a hormone regulating the recreative phase of carbohydrate metabolism and is therefore known as the 'rest hormone'.

Profs. Fyodor Primak and Vassily Vasilenko, of the same Institute, working under the direction of Prof. Nikolai Strazhesko, are studying a number of clinical problems in war medicine, in particular the working out of methods of oxytherapy. They are successfully continuing their study of the process of re-establishing the role of the hæmato-parenchymatose barrier in the human organism.

The Institute of Biochemistry has achieved very important results since the War began. The researches of Prof. Alexander Palladin, director of the Institute, into problems of the biochemistry of vitamins and the biochemistry of foodstuffs in general are of very great importance.

The Institute of Biochemistry is also carrying out research into the biochemistry of the nervous system and the biochemistry of muscular action in connexion with problems raised by clinical medicine, including the problem of the struggle against fatigue.

The Institute of Botany has been working since war began on the cataloguing and utilization of wild plants for defence purposes, and on increasing the output of agricultural products, both foodstuffs and industrial raw materials, to cover the needs of the army at the front and the people behind the lines.

The wild plant life of the Republic of Bashkiria, which is very rich in medicinal herbs, is being studied under the direction of Dr. Mikhail Kotov. A number of leaflets and pamphlets on the "Medicinal Herbs of Bashkiria" have been published. A number of wild-growing food and industrial plants are being utilized as the result of an Academy expedition.

The Agrochemical Section of the Institute of Botany has rendered great war-time service. Prof. Pyotr Vlasiuk has worked out methods of fertilization and farming processes for the cultivation of sugar beet and kok-saghyz, both of which are new crops in the eastern districts of the Soviet Union.

Prof. Nikolai Grishko, director of the Institute of Botany, is continuing his research into the sex genetics of hemp, employing the bi-sexual forms which he has produced in which male plants turn into female at the end of the vegetation period. The improvement of a sort of hemp which he produced earlier is being worked on. This sort is bi-sexual, both sexes reaching maturity simultaneously, making it possible to reap the crop entirely by mechanized methods.

Prof. Andrei Sapegin, who produced new sorts of winter wheat and barley which before the War were sown on 3,750,000 acres, is studying genetic processes of the reproductive organs of cultivated plants.

The laboratories of the Institute of Botany are working on new methods of the selection of hybrid pollen-bearing plants, in particular maize, and studying a number of problems in the cyto-embryology of plants. All this work aims at an increase in the output of agricultural products and an increase in war harvests.

OBITUARIES

Lady Lockyer

AFTER a long and active life devoted to wide social and scientific interests, Lady Lockyer, widow of Sir Norman Lockyer, died at Sidmouth on September 9, following a few days illness. She was ninety-one years of age, and her earthly body now rests in the little churchyard of Salcombe Regis close to that of her husband, who was buried there twenty-three years ago. The Norman Lockyer Observatory on the summit of Salcombe Hill is an outward and visible sign of the exaltation of their spirit to the skies.

Lady Lockyer was the younger daughter of Mr. S. W. Browne, and she with her sister, the late Miss Leigh Browne, became associated with Sidmouth from their childhood days through prolonged visits to their grandparents, Captain and Mrs. Carslake. When living in London they were students at Queen's College, which was founded in 1848 by F. D. Maurice, Henry Morley and other men of "light and leading" to provide scholarly training for girls. The two sisters took an active part in social work in Whitechapel associated with Canon and Mrs. Barnett at Toynbee Hall, and in other public affairs and women's movements. They were the prime movers in the establishment of the first hall of residence for women students in London. An appeal was made for funds to provide such accommodation for women students at University College and the London School of Medicine for Women, and in 1882 the Misses Browne took the lease of a house in Bloomsbury for a term of twenty-one years and placed it at the disposal of a committee appointed to carry out the project.

The first student to come into residence was Miss Cicely Ullman (later Mrs. Sidgwick), and the house was soon full. It became clear that a real need had been met and that further accommodation was required. Two adjoining houses were afterwards leased, but when the lease terminated it was decided to build a College Hall in Malet Street on a freehold site and large enough to accommodate 112 students. The foundation stone of this Hall was laid in October 1931, when Lady Lockyer gave an address on its origin and growth. The new Hall was opened by Queen Mary in 1932 and became the chief residential centre for nearly two hundred women university students in London, until it suffered very severe damage from enemy action during the present War.

Lady Lockyer was the widow of Mr. B. E. Brodhurst, F.R.C.S., when she and Sir Norman were married in 1903. In the same year Sir Norman was president of the British Association, and her gracious presence will be remembered by many members who attended the Southport meeting. Later, they left their London house and occupied one built for them facing the sea on the picturesque slopes of Salcombe Regis. After taking up residence in this house, Sir Norman decided that the summit of Salcombe Hill was admirably suited for an astronomical observatory, as it possesses an unbroken horizon in every direction. With characteristic energy he set about constructing an observatory on this site in 1912. About seven acres of land were presented for the site by Sir Norman and Lady Lockyer, and a number of their friends made generous gifts to build and equip this Hill Observatory, as it was first named. In 1916 the Observatory was formed into a corporation to promote its development, and all the lands, buildings and equipment were conveyed to that body. The name was changed to that of the Norman Lockyer Observatory and the management and control were vested in a council of astronomers and other men of science.

In addition to the land on which the Observatory is situated, Sir Norman and Lady Lockyer contributed during their lifetimes sums amounting to about £11,000 to the Observatory, as well as valuable instruments. Sir Robert Mond, who was chairman of the Corporation until his death in 1938, had a new photographic equatorial constructed and a building erected to house it, his gifts amounting to about £7,500. Sir Francis McClean presented the fine twin-telescope used by his father, Dr. Frank McClean, and other gifts amounting to about £10,000, and his brother, Captain W. N. McClean, has contributed about £5,000 to the funds of the Observatory in addition to designing the domes of the chief instruments and supervising their construction. No other observatory in Great Britain has been built, equipped and maintained on this rich scale of donations from private benefactors.

By Lady Lockyer's death, the Observatory is provided with additional means for its development, in which she always took the keenest interest, and of which she was the honorary treasurer until her death. She has bequeathed to the Observatory Corporation the freehold house at Salcombe Regis in which she and Sir Norman lived, and most of its contents, as well as about forty acres of land up to the summit of the hill on which the Observatory stands, and a farm of eighteen acres and a cottage. It is rarely that such substantial benefactions are made in Great Britain for the advancement of astronomy, though they are common in the United States. They ensure permanent provision for purely scientific research at a time when attention is chiefly concentrated on investigations of possible industrial or other practical value. All who are interested in the pursuit of knowledge and the intellectual expansion produced by it will pay grateful tribute to the spirit and service by which Lady Lockyer used her faculties and means with wisdom and social understanding, not only during her life, but also provided for the continuance of this influence after she had passed into silence.

Lady Lockyer was elected a fellow of the Royal Astronomical Society in 1923, a few years after the Society had decided to admit women into its fellowship. Her cheerful and stimulating presence will be greatly missed by all who came into contact with her and she will long remain in esteemed and cherished memory. R. A. GREGORY.

Mrs. Thoday

MRS. MARY GLADYS THODAY (*née* Sykes), whose death at the age of fifty-nine occurred on August 9, will long be remembered as a keen and versatile botanist. A distinguished student of Girton College, Cambridge, she obtained first-class honours in both the first and the second part of the Natural Sciences Tripos, after which she commenced research work in botany first as Bathurst student and later as fellow of Newnham College.

Attracted to cytological work, she published some interesting contributions on the structure and the division of the nucleus in Funkia and also some important accounts of the histology of several of the Laminariaceæ and the histological relations between Cuscuta and its hosts. But her active mind was many-sided in its interests, and even while engaged in the researches just mentioned she turned her attention to the anatomy and morphology of some of the peculiar vascular cryptogams like Psilotum and Tmesipteris, also of the Gnetaceæ; publishing accounts of first-rate importance of both groups in the *Annals of Botany* and the *Philosophical Transactions of the Royal Society*. She also collaborated with one of her contemporaries at Cambridge, David Thoday (now professor of botany at University College, Bangor) in work on the physiology of plants and in genetics. Those who remember the eagerness of her mind at this time are not surprised at the remarkable output of her scientific work.

In 1910 she married David Thoday, but family cares did not interrupt her botanical work, and when her husband was appointed lecturer in plant physiology in the University of Manchester she was elected honorary research fellow in the University, and in addition to her private investigations she took some share in the botanical teaching. On their removal to Cape Town, where Thoday was appointed to the professorship of botany in 1919, Mrs. Thoday joined her husband in the study of the flora of South Africa on extensive botanical excursions and also continued her investigation of the Gnetales, and at the request of Prof. Seward revised and completed the authoritative book on this group of plants which the late Prof. H. W. Pearson had left unfinished and on which she expended much time and labour. After the return of the Thodays to Great Britain, Mrs. Thoday's interest in botany continued, and she was appointed honorary lecturer in botany in the University College of North Wales.

During a visit to Canada with the British Association in 1924 she collected material of the minute mistletoe *Arceuthobium pusillum*, and an investigation on this plant was begun on the lines of her earlier work on Cuscuta, but it was left unfinished owing to her serious illness.

During the War of 1914–18, Mrs. Thoday threw herself actively into the constitutional movement for women's suffrage, and while in South Africa she became interested in native welfare and the complex racial problems which beset that country.

After a serious illness in 1925 public affairs again claimed her interests and she gave an increasing amount of her time and energy to the promotion of international understanding and goodwill. The deterioration of the European situation towards the end of 1938 played no small part in her tragic breakdown in health in 1939, from which she never fully recovered. Those who know the prodigious amount of secretarial and organizing work, as well as public speaking, which she accomplished during the years 1925–38, can well imagine how much she might have continued to contribute to botanical knowledge in a peaceful world. Her four sons are all serving overseas.

F. E. WEISS.

Dr. H. G. Baynes

DR. H. GODWIN BAYNES, who died on September 6, was the leader of the Jung school of analytical psychology in England. His chief interest was not always, however, directed towards the intangible gossamer of the soul. He was a man well over six feet high, with breadth not belying his height, and with physical powers that gave him his 'blue' and led him in his university days to row for Cambridge against both Harvard and Oxford.

Educated at Trinity College, Cambridge, he became house physician at 'Barts' during 1909–10. He acted as surgeon in the Red Crescent Mission to Turkey in the Balkan War of 1911–12, and after an interval of general practice at Wisbech became captain in the R.A.M.C., and in this capacity served in France, Mesopotamia and Persia. After the War of 1914–18 he took up a post on the resident staff at the Maudesley Hospital, and it was in connexion with his psychiatric work that he became, during 1919–22, assistant to Prof. (then Dr.) C. G. Jung in Zurich.

This was the turning point in Baynes' career. Henceforth his energies were devoted, both through the practice of psychotherapy and through the printed word as well as by means of numerous addresses to public and private bodies, to the dissemination of Jung's psychological doctrines. He not only translated Jung's major scientific work "Psychological Types" and edited and translated his "Contributions to Analytical Psychology" and "Two Essays on Analytical Psychology", but also wrote, in addition to numerous papers on psychiatry, medicine and folklore, a 900-page work entitled "Mythology of the Soul", and a last work on "Germany Possessed".

Baynes also organized and took part in the expedition which Jung made to East Africa during 1925–26 for the purposes of psychological research among the Massai tribes of Mount Elgon in Kenya.

Psychologists are apt to be thought of as formidable, if at times misguided, intellectuals. Baynes was far removed from such a category. Large-hearted as well as large-limbed, he added to his technical knowledge a warmth and sympathy that gave heart and assurance to those whom he helped to find their way, through the labyrinthine passages of the soul, towards that state of integration which results from a full recognition of the healing factors that lie buried in the collective unconscious in which he was such a firm believer. His loss is keenly felt by numerous patients and yet more numerous friends, and not least by the members of the Analytical Psychology Club in London, which he founded and led until his untimely death in full vigour at the comparatively young age of sixty-two.

John Layard.

Dr. L. F. Barker

Dr. Lewellys Franklin Barker, the eminent American anatomist and physician, who died after a long illness at Baltimore on July 13, was born at Norwich, Ontario, on September 16, 1867. He received his medical education at Toronto, Leipzig, Munich and Berlin, and qualified in 1890 at Toronto, where he worked at the general hospital for a year, and from 1894 until 1900 was attached to the Johns Hopkins University as associate professor of anatomy and pathology. From 1900 until 1905 he was professor of anatomy at Rush Medical College, Chicago, and for the next eight years was professor of medicine and chief physician at Johns Hopkins Hospital; he was appointed emeritus professor in 1921.

Prof. Barker was a prolific writer both on anatomical and medical subjects. His anatomical work included a translation of Spalteholz's "Hand Atlas of Human Anatomy" (1933), "Laboratory Manual of Human Anatomy" conjointly with Dean DeWitt Lewis and D. G. Revell (1904), and "Anatomical Terminology with special reference to the B.N.A." (1907); his chief medical works were "Tuesday Clinics at Johns Hopkins Hospital" (1922) and "Clinical Diagnosis of Internal Diseases" (1923), "Degenerative Diseases" with T. P. Sprunt (1925) and "Rheumatism; its Meaning and its Menace" (1926). He was also editor of "Endocrinology and Metabolism", by ninety-eight contributors (1922–24), in which he wrote part of the section on the parathyroid glands. His last works were "Psychotherapy" (1940) and his autobiography entitled "Time and the Physician" (1942).

In 1931–32 in honour of his sixty-fourth birthday, *International Clinics* published a Lewellys Barker *Festschrift* to which more than forty medical men contributed, including the well-known historian Fielding H. Garrison, who summarized his character as follows: "An austere devotion to duty and the things of the mind is set off by a distinction of appearance, a charm of personality, an hospitable nature, an open-minded freedom from prejudice, an innate kindliness of disposition, which are by no means least among the attributes of the beloved physician".

He received many honours, being hon. M.D. of the University of Toronto and LL.D. of Queen's University, Kingston, Ontario, and McGill University, Montreal. He was vice-president of the American Medical Association (1916–17), president of the Association of American Physicians and the American Neurological Association. He also enjoyed a European reputation, being foreign member of the Budapest Royal Society of Physicians, the German Society for Internal Medicine and Children's Diseases, the Medico-Chirurgical Society of Edinburgh and the Swedish Medical Society.

J. D. Rolleston.

Dr. H. C. H. Townend

Dr. Herbert Charles Henry Townend, who was accidentally killed on August 19, was born in London on March 18, 1896, and was educated privately. In 1915, he enlisted as a private in the Honourable Artillery Company and after receiving a commission in the London Regiment was attached to the Royal Air Force as an observer and served in Salonika, Egypt and Palestine. On returning to civil life, in 1919, he became a student at the Northampton Polytechnic, University of London, and obtained the B.Sc.(Eng.) (Lond.) degree, with first-class honours, in 1923. In October of that year he joined the staff of the National Physical Laboratory as a scientific officer. He took part in experimental work in the Aerodynamics Department covering a number of different subjects, but was best known to the outside world as the inventor of the Townend ring, a cowling device used to reduce the drag of the exposed cylinders of air-cooled engines. He made this discovery by accident when engaged on work with quite a different object, a chance observation directing his thoughts in a direction which ultimately led to the development of the ring. Townend was granted a patent on the device and it was at one time very widely used. For his work in this sphere he was awarded the Silver Medal of the Royal Aeronautical Society in 1931 and was awarded a D.Sc.(Eng.) (Lond.) in 1932. Dr. Townend was elected an associate fellow of the Royal Aeronautical Society in 1930 and a fellow in 1933. He was also an honorary scientific member of the Institute of the Aeronautical Sciences of the United States.

Townend's greatest contribution to the service of aerodynamics, however, was his fundamental study of the properties of turbulent flow. He devised an exquisite technique in which tiny spots of hot air were produced by minute electric sparks at various points in the field of flow to be examined, and the subsequent motion of these 'hot spots', as he called them, was observed by cinema-photography. By these means he was enabled to follow the details of the turbulent motion, and the results of his investigations have been of great value in the subsequent development of the subject. He was a brilliant experimenter, one of those rare men who can improvise apparatus out of almost nothing, fit it up with their own hands, and produce important results by its use. This characteristic showed itself also in his private life, for one of his favourite hobbies was the invention and construction of very clever, but very simple, mechanical toys, some of which reached the Patent Office and the general public.

In 1937, Townend left the National Physical Laboratory and joined the staff of the Admiralty as an adviser on aerodynamic problems. The nature of his work was now completely changed, and instead of making experiments himself on a particular subject, he found himself supervising the experimental work of others and taking a broad view of the whole field of aerodynamics as it affected the problems of the Fleet Air Arm. That he was as successful in this as he had been as an original investigator is ample testimony to his great gifts and his clear vision. He maintained a very close contact with the National Physical Laboratory and was a frequent visitor to his many friends and former collaborators there. He had a delightful personality, and was a very interesting conversationalist. His many friends will feel a deep personal loss, and the science of aerodynamics has undoubtedly lost one of its most brilliant exponents.

WE regret to announce the following deaths :

Dr. J. J. C. Bradfield, C.M.G., Australian representative on the Council of the Institution of Civil Engineers during 1936–39, formerly chief engineer of the Sydney Harbour Bridge, aged seventy-five.

Prof. A. E. Bunge, professor of statistics in the University of Buenos Aires and director-general of national statistics, aged sixty-three.

Mr. Paul R. Crimp, student probationer at the Laboratory, Plymouth, and whaling officer, Ministry of Agriculture and Fisheries, in North Africa, aged thirty-one.

Prof. H. Lundborg, professor of racial biology in the University of Uppsala.

Prof. J. M. MacFarlane, emeritus professor of botany in the University of Pennsylvania, aged eighty-seven.

Dr. E. J. H. Mackay, the well-known archæologist, on October 2, aged sixty-three.

Prof. Peter Mühlens, director of the Bernard Nocht Institute for Naval and Tropical Diseases, Hamburg, aged sixty-seven.

Prof. A. A. Read, emeritus professor of metallurgy in the University College of South Wales and Monmouthshire, Cardiff, on September 24, aged seventy-five.

NEWS and VIEWS

Fisheries of Mauritius: Appointment of Dr. J. F. G. Wheeler

DR. J. F. G. WHEELER, lately director of the Bermuda Biological Station for Research Incorporated, has been appointed marine biologist in Mauritius. Dr. Wheeler was assistant lecturer in zoology at the University of Bristol and during 1924–31 was naturalist on board the R.R.S. *Discovery* engaged on whaling investigations in the Antarctic, before taking up his duties at Bermuda. The object of the Mauritius appointment is to obtain for Mauritius the services of an expert to examine the marine and freshwater fisheries with a view to the possible establishment of a permanent fisheries control organization to improve existing nutrition standards of the islanders. It is hoped that Dr. Wheeler's researches may be a prelude to the establishment of a Fisheries Department for Mauritius as a permanent institution. The present scheme for the development of the island's fisheries has been made possible by a free grant up to £4,500 under the Colonial Development and Welfare Act, 1940.

Copernicus

THE Selby Lecture, delivered on May 27 by Sir Harold Spencer Jones, the Astronomer Royal, at Cardiff was on Copernicus (Cardiff: Univ. of Wales Press Board. 1*s*. 6*d*. net). The lecture covers much the same ground as the article by the Astronomer Royal contributed to NATURE of May 22, but a few additional points are worth noticing. For a long time after the publication of "De Revolutionibus", it was believed that Copernicus was the author of the prefatory note which stated that it was not necessary that the hypotheses advocated should be true or even probable ; it was sufficient that they should lead to results in agreement with observation. Although Osiander wrote the prefatory note without Copernicus's knowledge, this was not known at the time, and there was a widespread belief in the sixteenth century that Copernicus had advanced his theory merely as a mathematical device which he did not consider corresponded to any physical reality. Another very interesting matter should be mentioned. Although Copernicus accepted the value for the solar parallax found by Hipparchus, namely, 3′, which implied that an astronomical unit was about one twentieth of its true value, yet the relative mean distances of the planets from the sun, obtained by Copernicus, were remarkably accurate when compared with the most recent determinations. Objections to the Copernican system arose *inter alia* on the question of the distance of the stars, and opponents contended that Copernicus had assumed a great distance for the stars merely to obviate the serious difficulty that they showed no parallax. This was the main reason for the rejection of the Copernican system by Tycho Brahe, and his substitution of a geocentric system in which the sun and moon revolved round the earth, but all the other planets revolved round the sun. Copernicus would not commit himself to any definite statement regarding the infinite distance or otherwise of the stars, and Bruno is usually regarded as the pioneer of the conception of an infinite universe and an infinite number of worlds, though he was anticipated in this by Thomas Digges.

THE recent issue of *Polish Science and Learning* (London : Oxford University Press) is devoted to articles dealing with the life and work of Copernicus, prepared in connexion with the quatercentenary celebrations held earlier this year. One of these is by Sir Harold Spencer Jones, the Astronomer Royal (see NATURE, May 22, p. 573); another, by Prof. H. Dingle, was referred to in the same issue (p. 576). In addition, Prof. St. Kot has contributed an address entitled "The Cultural Background of Copernicus", which shows how greatly indebted Copernicus was to the University of Cracow for his cultural polish. From letters written at the time, we learn that his university life was spent in an atmosphere which favoured independence of thought, enthusiasm for research, and provided the opportunities for developing universal, unfettered personalities. Mathematics and astronomy were predominant in the University, and humanist poetry also took a prominent place. Cracow was the only university north of the Alps in the fifteenth century which had two chairs of astronomy, and several of Copernicus's fellow-students devoted themselves to the study of astronomy and geography. Although he carried out prolonged studies after leaving Cracow in Bologna, Rome, Ferrara, and Padua, the University of Cracow was the first to take an approving interest in his discovery, and the professors there were the first to use Copernicus's astronomical calculations.

H. Kucharzyk has an article entitled "The First Disciples of Copernicus in England (Early English Copernicana)", which deals with the evolution of astronomy in England in the second half of the sixteenth century. The first English scientific man who was a real adherent and ardent supporter of the Copernican idea was Thomas Digges (1546–59), who was known as an astronomer and also as one of the leading mathematicians of Elizabethan times. His work, "A Perfit Description . . .", which appeared in 1576, is regarded as the principal English treatise on the Copernican system printed before the second quarter of the seventeenth century. H. Kucharzyk has also a short article with the title "Copernicus as Economist, Statesman, and Poet", and shows Copernicus's knowledge of monetary questions. In his treatise "De Monetæ Cudendæ Ratio", published in 1526, he formulated the principle which was later known as Gresham's Law, that bad money in circulation with good will drive out the good. His work in political spheres, as a physician, administrator, commander-in-chief of the beleaguered city of Olsztyn, and also as a poet, is dealt with very briefly in this article.

Mass Asphyxia

IN the tube shelter disaster in March of this year 173 people (28 men, 83 women and 62 children) lost their lives as the result, not of enemy action, but of a woman's fall with a child as the crowd was entering the shelter in a reasonably orderly manner. Others fell on top of the woman and the child, and within a few seconds there was a pile of people 3–4 ft. high. Some three hours later all casualties had been cleared. Some people at the top of the pile were dead, some at the bottom were living. Almost the last person extricated was a girl of about seven, who walked to the first aid post without help. These facts and many more of interest are given by Dr. K. Simpson (*Lancet*, September 11, 1943) in what he claims to be the first detailed scientific record of this very rare type of accident. The paper records the results of autopsies done on the instructions of the Coroner on four selected cases and discusses the causes of the deaths. Simpson points out that the factors causing sudden deaths in the early stages of asphyxia are little recognized; such deaths are usually accidental or due to criminal action and can scarcely be reproduced for quiet physiological experiment.

The causes of the deaths of these people were found to be complex. The author points out that asphyxia is not a simple problem. The word means pulseless (from the Greek, *a-sphuxis*), and not prevention of breathing. Three of the cases autopsied showed changes quite out of keeping with prolonged asphyxia. Among other factors that may operate in such accidents are direct compression of the abdomen or chest, constriction of the neck, concussional head injuries, inhalation of vomit and "emotional, reflex neurogenic, local cardiac and more general tissue changes". Parallel factors operate in criminal strangulation and the author discusses these. People may die suddenly at the sight of approaching death or danger or even when they receive bad news or anticipate asphyxia. Impaction of food at the glottis or of water in drowning, garotting, strangling, blows or kicks on the neck, even a brisk current of cold air on the neck, may, in certain individuals, stimulate the carotid sinus reflex and, through this, may cause vasovagal arrest of respiration and the circulation. Bruises and violent hyperextension of the neck, inhalation of vomit, crushing of the chest or abdomen and similar injuries had occurred in the cases autopsied. The author adduces evidence of the rapidity with which local biochemical changes in the heart muscle and in the blood chemistry may occur in asphyxia. When some or all of the factors indicated above are operating together, death can occur very quickly, perhaps within thirty seconds. Apart from the public and biological interest of this paper, it should have, as the author indicates, considerable forensic value.

International Bird Preservation

A JOINT meeting of the British and Polish Sections of the International Committee for Bird Preservation was held in the hall of the Royal Geographical Society on September 25 with Mr. David Seth-Smith in the chair. Dr. Jul. Borucki, representing the Polish Section, spoke on the work for bird preservation done in the past in Poland, directing attention to the fact that Poland and Czechoslovakia set an example to the world by the establishment of the international reserve in the High Tatras. He spoke of the work of reconstruction which would be needed after the War and the peculiar problems of bird preservation which would have to be faced. In a message, Count Wodzicki, chairman of the Polish Section (now Consul-General in New Zealand) stressed the close links which had always existed between the British and Polish Sections; links which had been made closer by the British Section adopting the Polish Section for the duration of the War, an act which symbolized a tribute to the Polish naturalists who had not only lost property and all the results of their scientific work but also their lives.

Mr. Walter E. Higham showed his magnificent colour film of British birds. He took his representative and international audience all over Great Britain, showing in the most exquisite photography different types of landscapes and the birds that are found there: from a typical English garden to the moors and mountains of Scotland, the Lake District, woodlands, fields and hedgerows, the fens, sandy shores and rocky coasts—a film which indeed demonstrates the glories of Britain to the foreigner and should justly make any Briton proud. About thirty species of birds were represented, all of such beauty that it is difficult to make any special mention, but the shots of a shelduck feeding in a shallow pool and reflected in the water are perhaps the highest achievement gained by any Nature photographer. The Belgian Ambassador, in moving a vote of thanks to Mr. Higham, stressed the value of international co-operation in Nature preservation; he mentioned in particular the International Conference on the Preservation of the Fauna of Africa and the proposed conference for the preservation of the fauna of the Pacific, which had to be abandoned on the outbreak of war.

A Part-time Education Scheme

WE have received a copy of an illustrated booklet which is handed to every boy on entering the service of W. T. Henley's Telegraph Works Co., Ltd., and Henley's Tyre and Rubber Co., Ltd. This booklet outlines a scheme which is intended to enable all youths joining the Henley organization to see how they can train themselves for their careers. Every boy is given the option of undertaking a course of training extending over a period of years. Those who have shown that they can benefit from such privileges and have been accepted for the course are released one day a week from their normal works duties to attend approved classes at selected educational institutions near to their place of employment. They are expected to devote themselves wholeheartedly to the courses laid down for them during this day, and to attend a recognized educational establishment of their own choosing on at least one other evening in the week, for which purpose, wherever practicable, they will be released from shift-work or overtime. In addition, they must undertake to carry out the homework in connexion with their day course to the satisfaction of the education authorities. The subjects selected for the day periods are of a more serious and fundamental nature, but a good deal of freedom is given in the selection of subjects for the evening courses. Boys are paid for the time spent at the day establishment, and all fees, both for the day and evening courses, are paid by Henley's. The scheme is intended to produce better workmen, foremen and managers, and also better citizens; in addition to every encouragement being given to the boys to enlarge their mental outlook, physical training classes form an important part of the scheme.

Production of Crop Seeds

THE supply and distribution of seeds of agricultural and horticultural crops has been a problem of major concern since 1939 for countries isolated from Central Europe. The developments that have taken place in their attempt to achieve self-sufficiency in this respect are described in Joint Publication No. 5 issued by the Imperial Bureaux, "The Production of Seed of Root Crops and Vegetables" (price 3*s*.). The creation of the sugar beet industry in the United States market is perhaps the most complete of the accounts published, for it can now meet domestic needs, whereas during 1932–34 dependence on imported seed was absolute. Good results have been obtained with vegetable seed production in Sweden, and provided the right areas are selected the prospect seems promising in Australia, New Zealand and Canada. As regards Great Britain considerable progress has been made, and although Scotland appears to be outside the limits of economic seed production for all but a few vegetable crops, in England the chief advances lie in determining those areas where maximum seed yield can be expected. An interesting development is the investigation into the possibilities afforded by the tropical highlands and by those parts of the Empire which lie in the Mediterranean basin. Much information is provided on the varieties used, seed laws and regulations, and a useful index of crops and varieties is appended. Specialists or members of recognized scientific institutions who are in need of more complete references to the literature on any given section, or of more detailed information on special points, are invited to apply to the Imperial Agricultural Bureaux at East Malling, Aberystwyth or Cambridge.

Earthquakes in Central and South America

THE United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has found the epicentres of three recent earthquakes in Central and South America. The first, on June 30, occurred at 20h. 13·0m. U.T. from an epicentre near lat. 14·5° S., long. 74° W., which is just north of the town of Coracora in Peru. The focus may have been deeper than normal. The second, on July 4, occurred at 9h. 52·1m. U.T. from an epicentre near lat. 9° N., long. 84·5° W., which is near the coast south-east of the town of San José, and due south of the volcano Irazu in Costa Rica. The depth of focus in this instance was possibly 100 km. The third earthquake was on July 5 at 21h. 7·6m. U.T. from an epicentre lat. 17·5° S., long. 73° W., which is immediately off the coast west of the town of Mollendo in Peru. The depth of focus was normal. All these epicentres are in well-known seismic areas and all interpretations and determinations are tentative. Calculations were based on instrumental reports from the seismological observatories at Georgetown, Weston, St. Louis, Pasadena, Philadelphia, Fordham, Tucson, San Juan, Washington D.C., Burlington, Mobile, Buffalo, and Salt Lake City.

Parsons Memorial Lecture

THE Parsons Memorial Fund, which is administered by the Royal Society, made provision for a memorial to the late Hon. Sir Charles Parsons in Westminster Abbey, and for an annual Parsons Lecture to be given under the auspices of eight specified institutions and societies in turn which are concerned with the subjects most closely associated with Parsons' name. In accordance with the terms governing the appointment of the lecturers, the 1943 lecture, which is the eighth of the series, is to be given under the auspices of the Physical Society. It will be delivered at the meeting of the Society at the Royal Institution at 4.30 p.m. on October 15, by the Right Hon. Lord Rayleigh, who has chosen as his subject "Optical Topics, in part connected with Charles Parsons". Previous lectures have dealt more especially with other aspects of Parsons' work.

Interpretation of Patterson Diagrams

The direct F^2 Fourier series of Patterson[1] is one of the most powerful methods in modern crystal analysis, and many of its applications have been described from time to time in Nature[2]. Patterson's original result was derived as an extension of the application to crystals of the theory of scattering of X-rays in liquids made by Gingrich and Warren[3]. Patterson computes the weighted average distribution of electron density ρ about a point in the crystal, cell-size abc, volume v, by the relation

$$A\ (uvw) = \frac{1}{v}\int_0^a\int_0^b\int_0^c \rho(xyz)\rho(x+u,\ y+v,\ z+w)\,dx\,dy\,dz,$$

which gives the distribution about the point as a function of the parameters uvw. Making use of the usual expression for the electron density in terms of the structure amplitudes $F(hkl)$, namely,

$$\rho(xyz) = \frac{1}{v}\Sigma\Sigma\Sigma\, F(hkl)\ \exp 2\pi i(hx/a+ky/b+lz/c),$$

the function $A\ (uvw)$ is obtained as

$$A\ (uvw) = \frac{1}{v^2}\Sigma\Sigma\Sigma\ |F(hkl)|^2\ \exp 2\pi i(hu/a+kv/b+lw/c).$$

The importance of $A(uvw)$ arises because it will only be large when there are high values in $\rho(xyz)$ both at (xyz) and at $(x+u,\ y+v,\ z+w)$. Thus a peak in the function $A(uvw)$ at $(u_1v_1w_1)$ corresponds to an interatomic distance in the crystal defined by a vector the components of which are $(u_1v_1w_1)$.

The success of the method, of course, depends on the fact that the distributions $A(uvw)$, or vector maps, can be calculated *directly* from the crystal measurements, because they only involve the square of the structure amplitudes, which can be directly observed.

Although very useful in dealing with simple structures with only a few outstanding features, the Patterson method becomes involved when applied to structures with large numbers of similar atoms, such as organic structures in general, owing to the excessively large number of interatomic vectors the peaks of which mutually obscure one another in the calculations and defy resolution. The following simple technique has been devised in an attempt to deal with this situation.

It is convenient to restate the Patterson result in very simple terms. Consider a linear arrangement of atoms, co-ordinates $\theta_1,\ \theta_2\ \ldots\ \theta_n$ ($\theta = \frac{2\pi x}{a}$, where a is the axial length). If F_h is the structure amplitude for the hth order, then,

$$|F_h|^2 = (f_1\cos h\theta_1 + f_2\cos h\theta_2 + \ldots + f_n\cos h\theta_n)^2 + (f_1\sin h\theta_1 + f_2\sin h\theta_2 + \ldots + f_n\sin h\theta_n)^2,$$

f_n being the atomic scattering factor appropriate to the nth atom for the plane h. Expanding the terms in the brackets we obtain, with a slight rearrangement,

$$\begin{aligned}|F_h|^2 = {} & f_1f_1\cos h(\theta_1-\theta_1) + f_1f_2\cos h(\theta_1-\theta_2) + \ldots + f_1f_n\cos h(\theta_1-\theta_n)\\ & + f_2f_1\cos h(\theta_2-\theta_1) + f_2f_2\cos h(\theta_2-\theta_2) + \ldots + f_2f_n\cos h(\theta_2-\theta_n)\\ & + \cdot\ \cdot\ \cdot\ \cdot\ \cdot\ \cdot\ \cdot\ \cdot\ \cdot\\ & + f_nf_1\cos h(\theta_n-\theta_1) + f_nf_2\cos h(\theta_n-\theta_2) + \ldots + f_nf_n\cos h(\theta_n-\theta_n).\end{aligned}$$

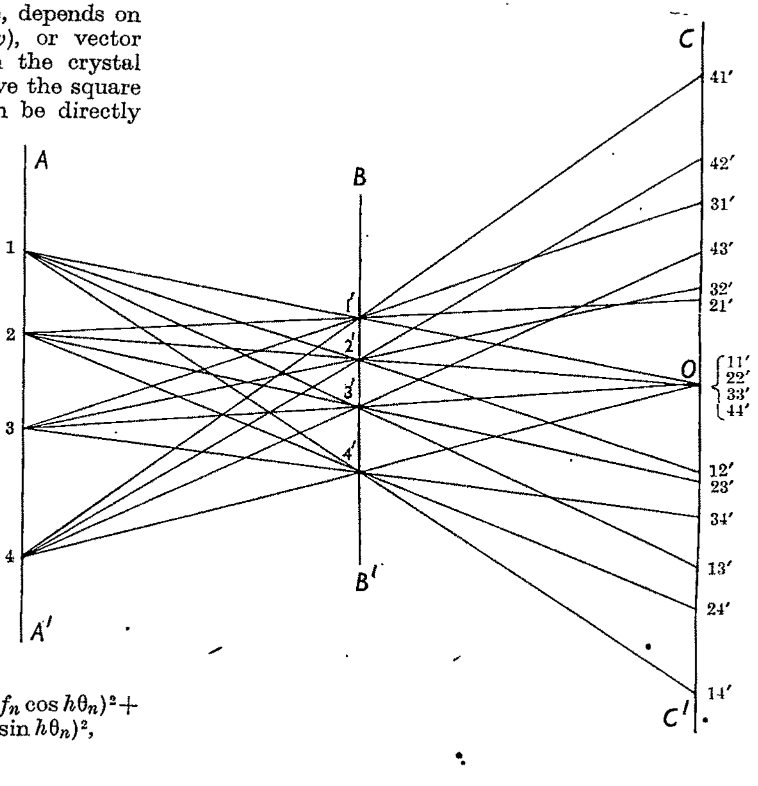
We note that the cosine terms contain all the interatomic distances in the structure, and that the coefficient of each term is the product of the atomic scattering factors appropriate to the pair of atoms concerned. This is, in effect, the Patterson result. Instead of a distribution of atoms or scattering centres, $\rho(x)$, we have to consider a distribution of interatomic vectors, $A(u)$. If this is represented by a Fourier series in the usual way, then the coefficients are $|F_h|^2$, of which there is an infinite series.

If the atoms are numbered 1, 2, . . . n, as above, the array of vectors may be written

$$\begin{array}{cccc} u_{11} & u_{12} & \ldots & u_{1n} \\ u_{21} & u_{22} & \ldots & u_{2n} \\ \cdot & \cdot & \cdot & \cdot \\ u_{n1} & u_{n2} & \ldots & u_{nn} \end{array}.$$

The diagonal terms $u_{11},\ u_{22},\ \ldots\ u_{nn}$ express the condition that every atom is at zero distance from itself, and the other terms $u_{12},\ u_{21}$, etc., occur in symmetrical pairs. There are thus only $\frac{n(n-1)}{2}$ terms which are essentially distinct. Nevertheless, this is a large number even for structures containing only a moderate number of atoms, and consequently there is little hope of locating the individual peaks in the Patterson diagram.

In this connexion the following simple construction is useful.



The points 1, 2, 3, 4 on *AA′* in the diagram are joined by straight lines to the point *O* on the parallel line *CC′*. The intersections, 1′, 2′, 3′, 4′, on some intermediate parallel line *BB′* are marked. A line is then drawn from each point on *AA′* to each point on *BB′* and produced to *CC′*. The array of points on *CC′* is then the vector map of the points on *AA′*. The construction is equally valid in two dimensions, with the points distributed on planes at *AA′*, *BB′*, and *CC′*.

If the points 1, 2, 3, . . . are movable light sources connected by thin elastic threads to *O*, and each thread carries a small light sphere at *BB′*, then the shadow pattern produced on the screen at *CC′* corresponds to the Patterson projection of the structure at *AA′*. The shadows will overlap and merge in some places, and in particular there will always be an intense shadow at the origin *O*, as in the Patterson distributions. The shadows can be adjusted to correspond very roughly to atomic contours by varying the size and intensities of the light sources.

The advantage of the method lies in the fact that as the atomic positions on *AA′* are varied, the resulting Patterson projection can be followed continuously. Now, the Patterson projection of any unknown structure can be calculated directly. To solve the structure, therefore, we have to vary the possible atomic positions until a good 'fit' is obtained. It is only rarely, of course, that one can deal with a small isolated group of atoms, as shown in the diagram. In general, parts of the adjoining unit cells will have to be included.

The method seems to have distinct possibilities in dealing with structures containing moderate numbers of similar atoms, and it is also an interesting lecture experiment. It is possible to abolish the rather troublesome threads and small spheres by using properly placed photographic plates and negatives, and the method outlined above also has the virtue of continuous variation.

J. MONTEATH ROBERTSON.

A New Criterion for Expressing the 'Intensity of Firmness' of Soft Bodies

Nutting[1,2] has proposed, and Scott Blair and Coppen[3,4], Broome and Bilmes[5,6], Couzens and Wearmouth[7], Lethersich[8] and Haward[9] have developed and applied, an equation expressing the shear strain (σ) in soft materials as proportional to a power (β) of the shear stress (S) and also to a power (k) of the time (t) of its application. This equation may be written:

$$\sigma = \psi^{-1} S^{\beta} t^{k}, \qquad (1)$$

where ψ is an intensity or proportionality factor which, unlike β and k, has complex dimensions.

Since $1/\psi$ is defined as the strain produced by unit stress in unit time, a comparison of the firmness of materials having different β and/or k values in terms of ψ is in any case arbitrary. Moreover, the usual unit of force (1 dyne) being very small compared with the stresses normally required, these values of ψ are not only arbitrary but are apt also to be misleading. Although this latter difficulty can be obviated by using a larger unit of force, ψ still represents no more than a point within a three-dimensional diagram.

The intensity factor cannot, in the nature of things, be expressed in terms entirely independent of arbitrary conditions: but a great improvement can be effected if we use, for purposes of comparison, instead of ψ, a property ζ, defined as the reciprocal of the volume of the $S : \sigma : t$ figure integrated between the limits of the greatest ranges of stress and time likely to be used in practical testing.

As an example, for materials which are readily deformed by squeezing in the hands ("soft bodies"), Scott Blair and Coppen[10] have shown that stresses of the order of 10^6 dynes/cm.^{2} are normally exerted. For studying such materials, a convenient range of stress would be 0–10^6 dynes/cm.^{2} and of time 0–100 sec.

Indicating these limits by their logarithms as suffixes, we have, for the volume of the selected figures:

$$1/\zeta = \int_0^{S_6} \int_0^{t_2} \sigma . dS . dt. \qquad (2)$$

Substituting from equation (1) and integrating:

$$1/\zeta = \psi^{-1} \frac{1}{\beta+1} \frac{1}{k+1} S_6^{\beta+1} t_2^{k+1};$$

or, writing σ_m for maximum strain and taking logarithms:

$$\log \zeta = \log (\beta+1) + \log (k+1) - 8 - \log \sigma_m \qquad (3)$$

Log σ_m can either be determined experimentally or, more usually, calculated from experimental data for lower values of S and t, using equation (1).

Scott Blair and Caffyn's[11] suggestion that the deformation properties of soft materials should be described by plotting log ψ vertically on the base of a 'Nutting square' having β and k as horizontal co-ordinates is thus improved by substituting log ζ for log ψ.

For the special cases of an elastic solid ($\beta = 1$, $k = 0$) and a viscous fluid ($\beta = 1$, $k = 1$) it is easy to express ζ in terms of shear modulus and viscosity. It is not, of course, a fluidity, in spite of its dimensions ($M^{-1}LT$), which are independent of equation (1). Notwithstanding the necessity for fixing limits in the integration defining ζ, this treatment often provides better criteria of the behaviour of complex materials under stress than do viscosities and shear moduli, since the former usually fall in a complex manner with rising stress and rise with increasing strain, and the latter are frequently dependent on the stress history of the sample.

I am indebted to Dr. F. M. V. Coppen and to Mr. L. Bilmes for helpful discussions.

Structure of the Eta Phase of the Iron-Silicon System

THE crystal structures of the different phases of the iron-silicon system have been worked out by Phragmen[1] with the exception of one, which he described as Fe_3Si_2 (25·0 per cent Si). This phase usually appears together with α (solid solution of silicon in ferrite) or ε (FeSi). The composition seems to correspond to 23–25 per cent Si, but it is difficult to obtain it in a pure form. Furthermore, Greiner and Jette[2] showed that the η phase was stable only between 825 and 1030° C.

Osawa and Murata[3] described this phase as Fe_5Si_3 (23·1 per cent Si) and succeeded in indexing the lines on the basis of a hexagonal unit cell with:

$$a = 6{\cdot}727_5 \text{ kX.}, \quad c = 9{\cdot}411_2 \text{ kX.}, \quad \frac{c}{a} = 1{\cdot}398_9.$$

Experimental work carried on here supports their conclusions except that we find the c axis to be only half this length[4].

It was then realized that the powder photographs of Mn_5Si_3 and Fe_5Si_3 show a great similarity. Comparative measurements of spacing, as well as observation of intensities, confirmed this analogy.

The structure of Mn_5Si_3 has been elucidated by Amark, Borén and Westgren[5]; the space group is D_{6h}^{3} (C 6/mcm), and not that previously suggested[4]. The unit cell contains $Mn_{10}Si_6$. The accompanying table gives the particulars of the Mn_5Si_3 and Fe_5Si_3 structures:

	Lattice parameters			Structural parameters[6]		
	a (kX)	c (kX)	$\frac{c}{a}$	4 Mn (or Fe) in (d)	6 Mn (or Fe) in (g) u = 0·23	6 Si in (g) v = 0·60
Mn_5Si_3	6·898 ± 0·005	4·802 ± 0·005	0·696	$\frac{1}{3}$ $\frac{1}{3}$ $\frac{1}{4}$	u u O	v v O
Fe_5Si_3	6·7416 ± 0·0006	4·7079 ± 0·0006	0·69834			

The reason why this similarity has not been noticed before is probably that different authors found some difficulties in deriving the right formula for the phase. Borén[7] studied by X-rays the alloys of silicon with chromium, manganese, cobalt and nickel. He observed the hexagonal phase in the Mn-Si system, but did not remark its similarity with the eta phase of the iron-silicon system. He attributed to the manganese-silicon phase the formula Mn_3Si, while the eta phase of the iron-silicon system was described as Fe_3Si_2. Actually, it now appears certain that they should be described as Mn_5Si_3 and Fe_5Si_3 respectively.

The analogy between the two systems is now evident, as the following comparison shows:

Mn_3Si is a body-centred phase (a = 2·851 kX)[5].

Fe_3Si, or the region of the continuous solid solution of silicon in iron corresponding to this particular composition, is also body-centred (a = 2·8220 kX. ± 0·0003).

Mn_5Si_3 and Fe_5Si_3 are isomorphous, as described above.

MnSi (cubic, a = 4·548 kX. ± 0·002)[8] has the same structure as FeSi (a = 4·4790 kX., the lattice parameter varying with the composition).

The structure of the eta phase was the only unknown one in the iron-silicon system, which is now completely worked out from the crystallographic point of view.

Approval for publication has been given by the Director-General of Scientific Research and Development, Ministry of Supply.

Variation of Serum Composition with the Age of Horses as shown by Electrophoresis

THE results briefly reported below became apparent during the course of systematic examination of samples of sera from a wide variety of sources. A simple modification[1] of the Tiselius electrophoresis apparatus[2] was used in conjunction with the Lamm scale method[3] of recording the migration of the serum components. On the graphs obtained the approximate area of that portion of the curve representing a particular component was measured and the figures expressed as percentages of the total protein. The protein concentrations are given in the table below.

It is apparent that serum of the newly born foal with a relatively low total protein content is characterized by a high albumin and α globulin, only traces of β globulin and a complete absence of γ globulin. At the age of five days the albumin has decreased to a concentration slightly higher than that of the adult animal; this is accompanied by a slight but scarcely significant increase in α globulins, a tremendous increase in β globulins and the appear-

Age of horse	Percentage of total protein				Protein conc.
	Albumin	$(\alpha_1+\alpha_2)$ glob.	$(\beta_1+\beta_2)$ glob.	γ glob.	
Newly born	65	32	3	0	3·7
After 5 days suckling	37	36	25	2	5·25
Foal, 8 months	33	14	25	28	6·8
2½ years	30	11	33	26	7·0
10 years	30	11	12	47	7·0

ance of traces of γ globulins. With age the albumins decrease slightly, and the α globulins markedly, to a constant. The β and γ globulins decrease and increase respectively in marked degree so that the total protein concentration remains constant at a figure slightly less than double that of the newly-born foal.

Jameson, Alvarez-Tostado and Sortor[4] reported results on the electrophoresis of calf serum. They showed that the increase in γ globulin is very rapid during the nursing period; in other respects their results resemble the results reported in this communication.

A New Source of Trehalose

ABOUT fifteen years ago the manna of the Sinai desert was identified by Bodenheimer and Theodor[1] as the excretion of the scales *Trabutina mannipara* and *Najacoccus serpentinus* on the leaves of *Tamarix mannifera*. Chemically, the manna was determined as a mixture of sucrose and invert sugar[2].

Recently, Prof. Bodenheimer kindly supplied me with specimens of a manna from the North Iráqian desert (Suleimanyia District). The Bedouin gather this sweet product from leaves of trees and bushes, and use it as a sugar substitute in coffee. It is a half syrupy, half crystalline mass, and is considered by Prof. Bodenheimer to be an excretion of a leaf scale. Chemical analysis showed that its sugar fraction consists mainly of the rare disaccharide trehalose, which could be isolated from the mixture after elimination of the fermentable sugar by yeast, deproteinization, concentration and extraction of the residue with boiling alcohol. It showed the correct optical activity: $[\alpha]_D + 198°$. One manna specimen contained 30 per cent and the other 45 per cent of trehalose calculated on the total dry matter, and 70 per cent and 80 per cent of trehalose calculated on the total carbohydrate content. The remaining carbohydrate consisted of sucrose and invert sugar containing an excess of glucose.

Previously, trehalose has been shown to occur in another rare manna (trehala-manna), which has been identified as the cocoon of an oriental beetle, and in yeast, other fungi, and species of Selaginella[3].

Microbiological Assay of Riboflavin

IN 1939, Evans, Handley and Happold[1] used the Strong-Snell[2] method to demonstrate the synthesis of riboflavin, among other elements of the B complex, by *C. diphtheriæ*, and early in 1940 I demonstrated to the Biochemical Society the Strong-Snell technique for the assay of this component. In further studies we became aware of certain pitfalls in the application of this method; our observations being communicated to fellow investigators at a symposium held in Reading a year ago.

Since then full papers on the microbiological assay of riboflavin by Barton-Wright and Booth[3] and by F. W. Chattaway and Mary Sandford and myself[4] have appeared. The formers' paper, which appeared first, does not mention at least two facts of importance which must be considered before the original method of Strong and Snell can be applied, namely, the importance of the calcium level of the medium, and of the additional growth factors, which must be present in the medium in optimal proportions. Both of these points have been conceded in private conversation. It is therefore to be regretted that in their recent communication to NATURE[5] which appears simultaneously with that of Prof. Hopkins[6] there is no mention of these particulars. It seems a pity that we should run the risk of discrediting a potentially valuable line of approach to the rapid assay of the vitamins of the B complex by failing to indicate to all workers in this field the necessity for careful and critical scrutiny of the methods in use before we apply them in a wholesale fashion to the analysis of foods and body fluids and secretions.

[5] Barton-Wright, E. C., Moran, T., and Sarson, H. S., NATURE, 152, 273 (1943).

[6] Hopkins, R. H., NATURE, 152, 274 (1943).

DR. HAPPOLD has shown us a copy of his letter criticizing the microbiological assay of riboflavin by our modification of the Snell and Strong[1] method. Had his criticisms been raised against the assay of pantothenic acid using *Lactobacillus helveticus* or nicotinic acid using *L. arabinosus* (Snell and Wright[2]) we would have been in partial agreement, but as regards riboflavin assay they have no justification.

Further, we would point out that our paper was submitted for publication a fortnight before the Reading symposium (held September 25, 1942), while we certainly have never conceded in private conversation the point that Dr. Happold raises.

The Snell and Strong medium uses photolysed peptone and yeast extract for the necessary remaining factors other than riboflavin required in optimum amount. The main reason for the success of the riboflavin assay by this method and lack of success with some other members of the B_2 complex is due to the fact that the riboflavin is easily removed from peptone and yeast without destroying the other factors. Peptone itself contains an unknown factor which is required in high concentration by *L. helveticus* and also *L. arabinosus* and *Streptococcus lactis* (Pollack and Lindner[3], and our own unpublished observations). Our main difficulty, for example, in the microbiological assay of nicotinic acid has been to free the peptone of its nicotinic acid without at the same time removing this unknown factor.

Chattaway, Happold and Sandford[4] have described a 'synthetic' medium using hydrolysed casein in place of peptone for the assay of riboflavin, and have stressed the need for $Ca^{\cdot\cdot}$ to be present. This medium, however, suffers from the fundamental defect that it contains no sodium acetate, and is therefore insufficiently buffered (Stokes and Martin[5] and our own unpublished observations). In so far as calcium chloride is a very much less satisfactory buffer than sodium acetate it fails to maintain the desirable *p*H for optimal growth and acid production—if a suitable amount of sodium acetate be present in the medium the presence of Ca ions has no effect one way or the other on the titrations.

Further evidence for the inadequacy of the medium used by Chattaway *et al.* is shown (1) by the fact that they were unable to obtain satisfactory values for the riboflavin content of certain foodstuffs; (2) the fact that its sensitivity in response to added riboflavin is very low—0·1–0·8 μ gm./10 ml. medium, cf. Fig. 1 (Chattaway *et al.*) with a maximum titration of 6 ml. N/10 NaOH. With the Snell and Strong medium the range of riboflavin used varies from 0·05 to 0·2 μ gm. and the maximum point is reached at 0·25 μ gm. The titration value here is between 17 and 18 ml. N/10 NaOH/10 ml. of medium.

Finally we would point out that it can scarcely be mere coincidence that assays carried out by the microbiological, fluorometric and biological methods on the same material all agree within experimental error (Barton-Wright and Booth[1], Copping[6]). This agreement has since been extended to mixed diets, the results of which will shortly be published.

An Alumina Hydrogel

SOLS of hydrous alumina are generally prepared either by the hydrolysis of aluminium acetate solutions, or by the peptization of freshly precipitated hydrous alumina. Such sols are converted to gels by the addition of a suitable small amount of electrolyte, and the gels so formed are thixotropic at concentrations so low as 1 per cent Al_2O_3 [1].

Pavelka[2] prepared an alumina sol by the addition of ammonia to an aluminium salt in the presence of boric acid. The following discussion shows how an alumina gel may be formed in the presence of boric acid without the addition of ammonia. The gel is formed simply by cooling a sol of suitable composition, as in the typical preparation of an organic jelly.

In the course of the colorimetric determination of silica in alumina, the alumina was brought into solution by fusion with a mixture containing 2 parts of sodium potassium carbonate to 1 part of anhydrous borax. The melt was afterwards extracted with water, and the aqueous solutions, under certain conditions of concentration and *p*H, were found, on standing, to be converted into gels which exhibited, to a slight extent, the phenomenon of thixotropy.

If a solution containing 4·45 gm. of Al_2O_3 and 17·8 gm. of fusion mixture in 100 ml. was allowed to stand in the cold, it was converted into a gel which, on shaking, was transformed to a viscous liquid. More concentrated solutions (5 gm. Al_2O_3 and 20 gm. of fusion mixture in 100 ml.) formed a brittle gel which became pasty on stirring. If left undisturbed, these gels soon regained their original firmness.

The sol-gel transformation is reversible, since, on warming, the gels were converted into sols. The time required for the cooled sols to be reconverted into gels was found to depend on their concentration. If the most concentrated sol was allowed to stand, a cloudiness and increase in viscosity was observed after half an hour, and the mixture set to a firm gel after an hour. If this sol was diluted to 2·5 times its original volume, so that it contained 2 gm. of Al_2O_3 and 8 gm. of fusion mixture in 100 ml., the cloudiness appeared after three hours and gel formation was complete after forty hours; if the solution was further diluted so as to contain 1·33 gm. of Al_2O_3 and 5·33 gm. of fusion mixture in 100 ml., the cloudiness appeared after twenty-four hours and a gel was formed after four days. All these gels suffered a marked decrease in viscosity on shaking.

In the most concentrated solutions a deposition of boric acid occurred, but this did not prevent gel formation.

The stability of these concentrated gels to acid was also investigated by acidifying the sol with nitric acid and testing its *p*H by means of the glass electrode before gel formation commenced. In this way it was found that a sol with *p*H so low as 2·4 was converted into a gel in the usual way. Addition of more 8 N nitric acid brought about the permanent destruction of the gel.

Production of Freshwater Fish in Palestine

IN his article on the "Freshwater Fisheries in the British Colonial Empire"[1], Dr. E. B. Worthington stresses the importance of freshwater fish production, but points out that in many parts of the Empire the fresh waters are being neglected. Taking Lake Victoria as an example, he estimates the production of fish in this great tropical lake to be only about 1·4 lb. per acre per year. This "ridiculously small" figure he compares with the North Sea which produces about 15 lb. per acre per year, and explains that in Lake Victoria only the fish of the inshore waters are taken, while the main mass of the water, 26,800 square miles in area, but less than 270 ft. in depth, is left undeveloped and unexploited.

It is interesting to compare these figures with those of Palestine where the fresh waters so far provide one quarter of the total fish production of the country. Apart from the Dead Sea, the largest area of inland water is Lake Tiberias (Sea of Galilee), which is a small, shallow sub-tropical lake, with an area of about 65 square miles and a depth of less than 160 ft. Despite the fact that the Lake has recently been seriously overfished, the catch during 1942–43 was 420 tons. This is a production of 22·5 lb. per acre per year, a figure about seventeen times as high as that of Lake Victoria. Investigations on the composition of this catch show that 76 per cent of the total was contributed by a small open-water cyprinid, *Alburnus sellal*, commonly known as 'sardine'. This little fish appears in the fishery only during four months of the year and is rarely taken above a length of 12 or 13 cm. The remaining 24 per cent of the catch was made up of three large species of Cyprinidæ and five species of Cichlidæ (Tilapia species and related genera) all of which are caught around the shores. If the catches of these inshore fish are considered separately, they show a production of 5·4 lb. per acre, a figure still nearly four times that of Lake Victoria.

The part played by the 'sardines' in the Lake Tiberias fishery is thus an extremely large one at the present time and one which has increased in importance in the last few years. In the past 'sardines' were considered of little value, and as recently as the 1935–36 and 1936–37 seasons, they contributed only 33 per cent of the total catch. The fishery then was not strictly controlled and the stock of fish was being both too intensively and irrationally fished, with the result that each year it was becoming increasingly difficult to get good catches of the larger cyprinids and cichlids. Although overfishing of these species was obviously occurring, the fact was masked in the records of the fishery since these showed a continuous increase in the total catch each year. The explanation is that as the other stocks decreased in size the fishermen turned more and more to the 'sardines' until three quarters of the catch was composed of them. This trend has been accentuated and accelerated by the new restrictions and regulations which were introduced into the fishery in 1942 to protect the stocks of the larger cyprinids and cichlids from destruction. These restrictions, as was expected, reduced markedly the catches of these fishes during the year 1942–43, making even more men concentrate on 'sardine' fishing. Luckily from the point of view of food production, the fantastic prices which the public of Palestine is willing to pay for fish of all kinds has encouraged the fishermen to work harder, so that the catch from the lake has not gone down as a result of the new legislation. Even the 'sardine', once spurned by all but the fellahin, is now in universal demand, and the other main species may realize more than two shillings a pound when landed on the quay.

The only other considerable area of natural fresh water in Palestine is Lake Huleh and its surrounding swamps. Last year this area produced 45 tons of fish. It is difficult to give a figure for production since the boundaries between open water, swamp and dry land are not clearly defined and vary greatly with the seasons. Taking the average area of water which can be inhabited by fish during the year to be not less than 9 square miles, the production is less than 5 lb. per acre per year. Since Lake Huleh is a shallow lake, rich in food, it is surprising to find that at present it is probably yielding less per acre than the inshore waters of the much more barren Lake Tiberias and only about one quarter of the total production of that Lake. In Lake Huleh more extensive cutting of channels in the weed beds is required if the fishery is to give its proper yield.

Turning to the subject of fish ponds, it is again interesting to compare the production in Palestine with that in other countries. In central Europe Dr. Worthington says that "fish farms may produce up to and more than 400 lb. of fish, such as carp and rainbow trout, per acre of water per annum". In Palestine exact figures are impossible as the industry is expanding rapidly, but during last year there were not less than 500 acres of fish ponds in existence which produced more than 200 tons of carp. The production, therefore, is between 800 and 900 lb. of fish per acre per year, which is at least twice as high as that of central Europe. This high figure results from the fact that carp grow very rapidly in the climate of Palestine. They become mature in a few months instead of in two years as in Europe, and may grow from the egg to a weight of more than four pounds in a year.

Polyploidy in the Potato

RECOGNITION of the polyploid nature of various economic plants has become increasingly important, and the type of polyploidy is also of prime importance in the study of phylogeny within any genus or family of plants. Various cytological and genetical criteria of polyploidy have been used, such as chromosome number, the number of nucleoli, polyvalent chromosomes in diakinesis, and tetraploid segregation ratios of genetic characters. In many plant genera, chromosome number together with the number of satellites, secondary constrictions and nucleoli (and where available with additional points in chromosome size and morphology) are sufficient to show the type of polyploidy and in some cases to provide adequate evidence as to how it has arisen[1]. In the genus Brassica, even the ancestral species have thus been clearly recognized in several cases[2].

In some genera, however, the distinction between allo- and autopolyploidy is difficult to make, even when considerable information, both cytological and genetical, is available. Cadman[3] and others have shown that in cultivated potatoes with $2n = 48$ chromosomes the chromosome number is probably tetraploid, but a genetical proof of auto- rather than allotetraploidy is by no means simple, partly owing to crossing-over and what has been called double reduction of the particular genes concerned. Other workers with the potato have regarded it as functionally a diploid, a view which is still not entirely excluded, although the chromosome number is evidently at least tetraploid.

In a recent note, Cadman[4] finds from 2 to 9 multivalent chromosomes in the pollen mother cells of the variety Flourball, the large majority being quadrivalent, with a few of even higher valence. As many as 8 quadrivalents were found in one cell (where 24 bivalents might be expected in a simple allotetraploid), suggesting the presence of 8 chromosomes which are at least partially represented in quadruplicate. The presence of high multivalents has also been shown in potato varieties by other investigators, indicating segmental interchange, which is well known to be of frequent occurrence in plants, such as the potato, which reproduce mainly by vegetative methods.

While this evidence increases the likelihood of autotetraploidy in the potato, it by no means constitutes proof. Studies of the nucleoli and their relation to the satellites have given such clear evidence of allo- or autotetraploidy in many other plant genera that a similar study of nucleoli in the potato is obviously called for. If, following the Feulgen stain, a green dye is used after an alkaline mordant[5], significant results should be obtainable without difficulty.

Apparent Reversal of Position of the Golgi Element in the Renal Tubule

THE work of Goormaghtigh[1] in elaborating on and extending Ruyter's discovery[2] of specialized cells in the renal arteriole, when taken along with Zimmerman's description[3] of an aggregation of the cells in the adjacent distal tubule, which Zimmerman called the *macula densa*, has introduced new terms and concepts into the histology and pathology of the kidney. It has already been shown that the tubule and the glomerulus which are in such intimate contact at the glomerular root are parts of the one nephron, and that both structures—the arteriole and tubule—seem similarly affected in disease[4]. Because of these facts and since Goormaghtigh has described both tubule and vessels as being jointly affected in several experimental procedures, we had suggested the term *juxta-glomerular complex* to serve as an all-inclusive term for these structures forming the glomerular root.

Apart from the aggregation of nuclei, distinctive features have been lacking for the cells comprising the *macula densa*. Goormaghtigh[1] described the centrosome in the *macula densa* as being situated on the side of the nucleus towards the attached pole of the cell, but other features to suggest a special function have not been described. Studies were undertaken with various techniques for the Golgi element in an attempt to supply this deficiency.

Kittens were killed rapidly with ether, and kidney blocks were prepared by the Da Fano and Mann-Kopsch (Weigl) techniques. In addition, rabbits were killed, each by a single blow on the head, and blocks of kidney tissue were prepared by the Aoyama, Champy post-osmified (Kolatchev) and Mann-Kopsch (Weigl) techniques. In every instance, the osmium preparations were of little use, whereas the silver impregnations (Da Fano and Aoyama) were quite satisfactory. It was found that toning of the sections for five or ten minutes in gold chloride (0·1 per cent containing a few drops of glacial acetic acid per 100 c.c.) appeared to increase the clarity of the images of the Golgi structures.

The appearances of the Golgi structures in the cat and rabbit kidneys are essentially similar. Without enlarging further on the appearance of these structures in the various segments of the renal tubule, suffice it to say that they were seen as granules and short rods. Their position in most tubule cells is remarkably constant, almost invariably being immediately on the lumen side of the nucleus. In the distal tubule a similar position is found except in the cells of the *macula densa*, where the position in respect to the nucleus seems to be reversed and the Golgi element appears to lie on the side of the nucleus towards the attached pole of the cell.

One will not attempt to infer any significance from this apparent reversal of the Golgi element. It may be suggested that if any autonomy existed in the blood supply of the mammalian nephron, the strategic situation for such an effect to be put into action seems to be the juxta-glomerular complex. This autonomy might consist of the regulation of the intermittency of glomerular flow, if such exists, or alteration in the pressure in and about the tubules, or in the afferent and efferent arterioles.

Further studies are in progress on the Golgi element in the kidneys of various other species and will be reported later in detail. It is felt that the cytological aspects of normal and abnormal physiology have been neglected, and that cytological techniques might add something to our information about the normal and diseased human kidney, among other organs.

I am grateful to Dr. John R. Baker of the Department of Zoology and Comparative Anatomy, Oxford, for his advice, encouragement and unfailing help in these studies; and to him and to Prof. E. S. Goodrich, through whose kindness it was possible to confirm some of this work in their department.

Competition for Nitrogen between the Take-all Fungus and the Roots of Crop Plants

SURVIVAL of the take-all fungus (*Ophiobolus graminis*) in buried infected cereal stubble is prolonged by an adequate supply of soluble nitrogen from the surrounding soil[1,2]. If the soil is left in clean fallow after harvesting a cereal crop affected by the take-all disease, then the ammonia and nitrate nitrogen set free by the activities of soil micro-organisms will become available to *O. graminis* in the buried infected cereal stubble, and the survival of the fungus is likely to be prolonged. But in soil under crop, much of the nitrogen thus set free will probably be taken up by the plant roots before it can reach *O. graminis*. With this possibility in mind, I have recently compared the survival of *O. graminis* in lots of 250 lengths each 1½ in. long of infected wheat straw buried in fallow soil, and in soil under trefoil, mustard, and oats, respectively. Eight weeks after burial of the infected straws in the soil, the percentage of straws containing viable mycelium of *O. graminis* (as revealed by a wheat seedling test[1]) was 68 under fallow, 18 under trefoil, 17 under mustard and 4 under oats.

Although due allowance must be made for the fact that this experiment was carried out in boxes of soil and not in the open field, it seems safe to conclude that the take-all fungus is likely to disappear more quickly from soil under a non-susceptible crop than from soil kept fallow. This observation may explain the success of a system followed by certain English farmers for continuous barley growing. Barley is susceptible to the take-all disease, and the second or third consecutive barley crop on the same land is sometimes severely attacked. But barley undersown with trefoil (which makes a luxuriant growth in late summer and autumn after the barley has been cut, and is then ploughed in as a preparation for the next barley crop) has not so far been observed to suffer from take-all. To explain this observation, it is suggested that the active growth of the legume after barley harvest keeps the available nitrogen content of the soil at a very low level, with resulting detriment to the longevity of *O. graminis*, most of which is unable to survive until sowing of the new barley crop in the spring.

Vacuum Filtration of Sewage Sludge

IT is interesting to know[1] that the results of experiments on the aeration of sewage sludge, as a preliminary to coagulation and vacuum filtration, may shortly be published by the Rivers Department, Manchester.

In Great Britain, the first experiments on vacuum filtration of activated sludge appear to be those carried out at Sheffield sewage works by the late John Haworth[2], and mentioned in a paper published by him in 1923. During the discussion on this paper, it was stated that by further aeration of surplus activated sludge in separate tanks, it is possible to bring it into a condition in which a great deal of water can be drawn off and the sludge can be more easily filter-pressed.

It is unfortunate that the results of subsequent experiments at Sheffield, by Howarth and J. H. Edmondson (his successor), have not been published. The latter has been working on the subject for the past seven years and, in his early experiments, found that activated sludge is most easily filtered when in a nitrifying condition and within three to six hours after leaving the sewage purification plant. In a tentative scheme which Edmondson has prepared, it is intended to store surplus activated sludge in a bio-aeration plant, designed for the dual purposes of aeration and equalizing the flow, previous to vacuum filtration.

Nutritional Research in the Crown Colonies

PROF. C. M. YONGE[1] refers to the need for the establishment of a centre of marine research in the West Indies, and further, he urges the creation of a fisheries' station there, after the War.

In 1941, I wrote to the *Lancet*, putting forward a similar requirement for nutritional research centres in the Crown Colonies. As yet, they possess no such organizations, as we see, for example, in India (Coonoor) or in China (Henry Lester Institute), to say nothing of the relatively great number of research units in Great Britain. Apart from the very obvious nature and even elementary considerations of such need, the Crown Colonies—with their severe incidence of deficiency disease states out of all parallel to our own country—afford quite exceptional opportunity for sustained nutritional research, as for example, their *different* dietaries, the *different* or apparently different factors which lead up to the same expression in types of disease, in *different* races and peoples. Again we have to remember, also, all nutritional investigation we should undertake in these Colonies primarily affects the welfare of those peoples, not ourselves.

Research institutes not only afford opportunity for research, but they also provide facilities for local training within the country concerned, and they offer security of tenure for the locally trained man. Many Indians, trained at Coonoor, now are not only contributing to the solution of many of their own food problems, as they should be, but also have become well-known authorities in a much wider field. Little of such opportunity has been given to our Crown Colonies, with the comparatively few exceptions of expensively trained home men, and even so, without the full facilities, there has been little enough opportunity for sustained or inclusive research.

Similar research centres, therefore, are long overdue, not only for the West Indies but also for West Africa, East Africa and so forth.

James Prescott Joule and the Unit of Energy

PROF. H. S. ALLEN's communication in NATURE of September 25 prompts me to mention a recent conversation which I had with a Manchester man whose evidence I should have considered trustworthy. He mentioned that in his youth he had known a man who had been well acquainted with Joule, and that he had told him that Joule himself always pronounced his name 'Jole', with the first vowel as in 'Joe'.

I should be interested to know whether there is any corroboration of this third possible pronunciation.

A. W. V. MACE.

Rugby School Science Laboratory,
Barby Road, Rugby.

FURTHER to Prof. H. S. Allen's communication in NATURE of September 25, I may say that Joule used to live not far from my home at Sale, near Manchester, and I have often seen his house. His name was pronounced 'Joole', thus confirming Prof. G. W. O. Howe's pronunciation.

GRAHAM RENSHAW.

30 St. Ann Street,
Manchester, 2.

RESEARCH ITEMS

Shell Fish-hooks of the Californian Coast

The Bernice P. Bishop Museum Papers for May 1942 include a useful account by Eugene Robinson of the types of shell fish-hooks in use on the Californian coast, and of the method of their manufacture. These hooks from the Santa Barbara Channel are of the circular type familiar in Polynesia and Micronesia, and are made by means of chert drills and stone files from pieces of shell cut to a flat pear-shape. Mr. Robinson explains how the circular hook, which looks so unpromising to a European fisherman, works in practice and is so satisfactory that steel hooks of similar pattern are sold in the stores of Honolulu. There must be no striking with these hooks; the fish hooks itself, and, with a gentle tension on the line, the hook turns over through the thin tissues at the edge of the fish's mouth, securing it more safely than an ordinary steel hook with a barb.

American Anchovies

Samuel F. Hildebrand gives a detailed review of the fishes of the family Engraulidæ in his paper "A Review of the American Anchovies" (Family Engraulidæ) (Bingham Ocean. Collect., Peabody Museum of Natural History, Yale University, *Bull.* 8, Art. 2, 1943). The anchovies are becoming increasingly important economically and, besides being fished commercially for food, are preyed upon by man, fishes and birds, and are also used extensively for bait. The review is very complete and contains descriptions of seventy-seven species and sub-species, nineteen of which are new. Keys are given to all the species in each genus and figures of most of them. They are carnivorous and typically pelagic shore fishes, usually moving about in schools, though sometimes taken singly at depths as great as 20–30 fathoms. Many ascend freshwater streams, especially in South America, where several species are found in the Amazon basin, a few of them in its upper tributaries. The author recognizes only one species apparently common to both Atlantic and Pacific coasts, *Anchoa spinifer*, and thinks it possible that even here specific differences may yet be found. The number of species from the Pacific recognized in these studies is only about two thirds as great as the number from the Atlantic, the chief home of the American Engraulidæ being in tropical and subtropical regions.

New Species of Fish

Henry W. Fowler describes a large number of new fishes from Florida, Eastern Brazil and Hawaii ("Notes on Florida Fishes, with Descriptions of Seven New Species. A Collection of Freshwater Fishes obtained in Eastern Brazil", by Rodolpho von Ihering. The George Vanderbilt Oahu Survey—The Fishes. *Proc. Acad. Nat. Sci. Philadelphia,* 93; 1941). The several collections noted in the first paper contain an interesting tide pool series from Florida made by Baldouin Lucke, showing early stages of development in certain species. The vernacular names are given in most cases in those from eastern Brazil making this paper of special value. In the third paper special attention is paid to colour, from notes made from the freshly received specimens, many of which remained brilliant for a long time. All these contributions are very well illustrated. Dr. Fowler has also published recently a series of short notices on fishes from 1939 until 1941 (Notulæ Naturæ of the Academy of Natural Sciences of Philadelphia).

Oysters of the Western Atlantic

Richard A. McLean attempts to classify the family Ostreidæ (*Notulæ Naturæ,* No. 67; Jan 14, 1941. Academy of Natural Sciences of Philadelphia). T. C. Nelson (1938) has shown that the correlation between the depth of the valve and the position of the muscle scar is of great anatomical importance. In the forms with a relatively deep cavity in the valves and an accompanying posterior position of the adductor muscle there is a water chamber anterior to and running dorsal from the right epibranchial chamber—called by him the promyal chamber. It is open at the top and water is expelled through this channel to the outside in addition to the usual course. The possession of this chamber has a definite survival value, such oysters being able to live in more turbid waters than those without it: moreover, the type of reproduction is different in the two forms, those with the chamber being diœcious and oviparous whilst those without it are hermaphrodite and larviporous. The present author uses these facts for separating two sub-genera of the genus Ostrea when the anatomy and type of reproduction are known. There is only one genus in the family with the subgenera Ostrea s.s., without promyal chamber, and monœcious, incubating the large embryos in the gill lamellæ, and Crassostrea, the type being *Ostrea virginica,* with promyal chamber, and diœcious, discharging the seminal products directly into the water.

Longevity of Paramecium

L. L. Woodruff (*Proc. U.S. Nat. Acad. Sci.,* 29, 135; 1943) reports that about 21,800 generations have taken place in a culture of *Paramecium aurelia* since it was started in 1907. No conjugation has been observed, and it would, therefore, seem that the vitality of these unicellular organisms is preserved without conjugation. The possibility of endomixis, of course, must be considered; nevertheless, the fact that the rate of division and general vitality of the culture has remained constant without cross-fertilization is notable.

Polyploidy and X-ray Dosage

K. Fröier, A. Gustafsson and O. Tedin (*Hereditas,* 29, 145; 1943) show statistically that on wheat and oats the effect of X-rays upon mitosis in dormant seeds differs significantly between diploids, tetraploids and hexaploids. Hexaploids possibly provide a straight-line curve of X-ray dosage, whereas diploids and tetraploids show a sigmoid curve. The authors suggest that it would be wise to re-investigate straight-line proportionality especially at low dosages of X-ray.

Soil Conditions in the Plant Pot

The greater volume of work on soils has been carried out on open ground, and relatively little is known, apart from culture experiments, about the limiting conditions of growth in a plant pot. Two papers by A. G. Pollard and C. W. R. Smith (*J. Roy. Hort. Soc.,* 68, Pts. 7 and 8; July and August 1943) describe some preliminary experiments upon the special conditions in such small units of soil. Levels of the major soil nutrients are higher in the field than in pots, and are higher in pots indoors than when placed in the open. Glasshouse conditions, moreover, produce the greatest ratio of shoot to root. Part of the disappearance of soluble matter from soil in pots is probably due to the action of the earthenware wall, and lime is removed in greater proportion than phosphate and potash. The papers are very suggestive, and some extremely useful results should accrue from a continuance of the investigation.

Granitization of Hornfelsed Sediments

A DETAILED field, petrological and geochemical study of the hornfelsed Silurian sediments enclosed within the Newry granodiorites of Goraghwood Quarry, Co. Armagh, has been made by Doris L. Reynolds (*Proc. Roy. Irish Acad.*, 48, B, No. 11, 231–265 ; 1943). It is established that two major changes are involved in the granitization process. The preliminary change was the metasomatic development of irregular bodies, lenticles, veins, etc., of porphyritic trondhjemite from two varieties of biotite-hornfels ; a change involving the fixation of migratory Na_2O, CaO and SiO_2, with concomitant driving out of other constituents. Migratory MgO and FeO, together with an appropriate amount of K_2O, can be traced in the rims of biotite and cordierite enrichment which are characteristically developed around the granitized bodies. The second major change was the development of porphyroblasts of microcline, and of bodies of granodiorite, adamellite and granite-pegmatite, both from earlier-formed masses of trondhjemite and directly from biotite-hornfels. This change involved the fixation of K_2O, an immediate source for which is found in the migratory K_2O liberated from the hornfelses during the preliminary soda metasomatism. A third variety of metasomatism is the conversion of diopside-hornfels to biotite-hornblende-plagioclase hornfels, which is chemically and mineralogically equivalent to quartz-biotite-diorite. The chemical data indicate that the minimum introductions necessary to initiate the complex geochemical migrations were sodium, calcium and silicon, and that all the other constituents can be adequately accounted for as derivatives from the hornfelses themselves. At the completion of the granitization process at one place the unfixed balance of sodium, calcium and silicon travelled on, to recommence the granitization cycle at fresh loci. Repetition of the process continued until the supply was exhausted. It is concluded that the introduced materials were passing through and/or emanating from the granodiorites at the time of their crystallization. The problem of their ultimate source lies outside the scope of the investigation and remains to be tackled by further work elsewhere.

Polymerization of Hydrogen and Deuterium Fluorides

THE vapour densities of these compounds over a range of temperatures and pressures have been redetermined by R. W. Long, J. H. Hildebrand and W. E. Morrell (*J. Amer. Chem. Soc.*, 65, 182 ; 1943). The highest degree of association found was 4·5, the association factors for deuterium fluoride being appreciably higher at each temperature than those of hydrogen fluoride. A previous proposal by J. H. Simons and J. H. Hildebrand (*J. Amer. Chem. Soc.*, **46**, 2138 ; 1943), although it has not been substantiated by subsequent work, is again considered in relation to the experimental results : it assumes that only hexamers are present in the polymerized product, $6HF = (HF)_6$, and is found to represent the results fairly well, although there is indication of lower polymers at lower degrees of association. This agreement is not regarded as amounting to proof of its sufficiency.

An Analysis of British Meteor Data

J. G. PORTER has published a paper with the above title which reveals the unsatisfactory nature of some of the old methods for computing the real paths of meteors (*Mon. Not. Roy. Astro. Soc.*, **103**, 3 ; 1943). In many cases, more especially in Denning's lists, preconceived opinions were formed regarding the position of the radiant, and the paths recorded by the observers were adjusted to fit in with this. The result was that systematic and accidental errors made by observers were obscured by the non-systematic errors allowed by the computer of the real paths. The value of such a procedure became more obvious when paths were recorded by more than two observers ; in many such cases very drastic adjustments were necessary, and in addition, in many of the doubly observed meteors it is shown that real paths and radiants were computed when there were no accordances at all. It was realized many years ago by the Meteor Section of the British Astronomical Association that the old method, which was still in use, was most unsatisfactory, but it was not until 1936 that an entirely new method was developed by Davidson, and the Computing Section of the British Astronomical Association immediately undertook the reductions under the directions of Porter. It is interesting to notice that of 232 paths published by Denning, where original data were available, it was necessary to reject 60 as being of zero weight, and in 172 of the remainder serious discrepancies between heights, lengths of paths, and speeds, exist when Denning's results are compared with those of Porter. Altogether 1,253 reductions have been made by the new method and results have been published from time to time (*J. Brit. Astro. Assoc.*). In the present paper Table 1 gives multiple accordances from 1892 to 1940, a total of 61, and Table 4 supplies results for the old accordances from 1865 to 1928. A very full discussion of errors is embodied in the paper, and it is shown how Prentice's technique for observation has introduced a considerable improvement in the results. It is hoped that further research will settle finally the vexed question regarding hyperbolic meteors, which British observers are very reluctant to accept.

Cleaning of Mirrors before Aluminizing

A paper with this title by Vladimir Vand (*J. Brit. Astro. Assoc.*, **53**, 7 ; 1943) provides an interesting account of the troubles encountered in the new process of aluminizing mirrors. These are divided into four chief classes : (1) Imperfect cleaning of the mirror. It has been found that a layer of impurities, even if only one molecule thick, between the glass and the coating, affects the coating very seriously. (2) Imperfect vacuum which is sometimes responsible for brown or black deposits. (3) Dirty aluminium and/or tungsten spirals which are responsible for impurities being evaporated on the mirror, and then aluminium is deposited on top of these. (4) The deposit is too thick, and when this occurs a milky deposit sometimes results. The paper deals very fully with these difficulties and with the methods adopted for overcoming them, and those who have had their mirrors aluminized will appreciate, from a perusal of this paper, the enormous amount of care and attention which are necessary if satisfactory results are to be obtained.

THE PLANE TREE

By ALEXANDER L. HOWARD

Travellers from warm and sunny countries criticize, quite rightly, the smoky atmosphere of London. It is a curious but fortunate fact that this damp and smoky climate, which retards the growth of nearly all forest trees, for some unknown reason invigorates the plane (*Platanus orientalis* Linn., *P. occidentalis*, *P. acerifolia* Willd.).

Throughout the City and its suburbs this lovely tree flourishes in all its grandeur and beauty, and completely outclasses other varieties introduced from foreign lands. For example, the acacia cannot live in England up to its national reputation in America, and has utterly failed to fulfil Cobbett's well-known claims.

It would probably be impossible to find a more beautiful avenue of trees than that which leads up the Mall to Buckingham Palace. These trees are now in their youth, and should grow in dignity for at least another two centuries, but already their spreading beauty in summer and their equally imposing winter aspect are unique. Planted and spaced at regular intervals, without failure or exception they have grown to a uniformity in size, both as regards the crown and the trunk. No other tree but the plane could be relied upon for such regularity of growth, and it is partly for this reason that it is so suitable for avenue and roadside planting.

Whilst all Londoners are familiar with its grace and beauty, and grateful for its cool shade in dusty summer heat, it is doubtful whether many realize the history of this interesting foreigner, which has become so happily naturalized in Great Britain. Indeed, such is our national ignorance and lack of education on this important subject, that only a small minority of English people know the difference between a plane and any other forest tree, despite its annual habit of shedding its bark, which is its own original and destructive way of keeping healthy.

Its tenacity and stubborn resistance to violent attack has been exemplified. "A fine plane tree can now be seen flourishing by the side of the Grand Junction Canal in London, close to the North Gate of Regent's Park leading to Avenue Road. It has an interesting history. In 1874 a barge containing petroleum, while passing up the canal, exploded with a report which was heard ten miles away. The bridge and the keeper's cottage were blown away, the plane tree being apparently destroyed. Thirty years after, the only part of the old trunk remaining was a dead, charred, pointed piece, which could be seen protruding through the new and vigorous growth around it; this dead piece has now disappeared (1932), and the only sign of the disaster which remains is an opening extending from the ground to about 10 feet from the present top of the tree. This opening is now closing, and it is safe to predict that in a very few years the trunk will no longer bear any evidence of the damage". This opening is now (1943) scarcely noticeable.

The Times has quoted another instance of what the contributor called "The Dauntless Tree", namely, the plane tree outside Stationers' Hall, which, "in spite of fire and bombs which stripped it of all its leaves and branches, put forth new leaf all up its abnormally straight stem, symbolising the dauntless spirit of London".

An admirable picture was produced in the *Tree Lover*, entitled "Bath after the Blitz", showing five plane trees in the demolished Circus; it now transpires that these trees are much less damaged than was originally thought to be the case.

From earliest times history records examples of the prominent position held in arboriculture by the plane tree, which was introduced first into Greece, and afterwards into Italy, and afterwards throughout all Europe, southern Asia, and in Persia, where the magnificent 'Chenar' trees have been the pride of its people. Continual reference is made to the plane tree before and after the rise of the Roman Empire. About the year A.D. 530 Pliny tells us:

> "But who would not marvel rather at this, that our people here should go into farre countries, and fetch a tree from thence, even out of another world, only for the shade that it giveth. For surely of fruitful trees Italie hath store ynouth. And what tree should that be but the very plane, brought first over the Ionian Sea into the island Djomedea, for to beautifie the tomb of Diomides. From thence translated into Sicilie and so bestowed at length upon Italie; and there planted, as a most regular, rare, and special tree. But now it is caried as far as Tetwin and Tournay in France, where it is counted an appertenance to the very soile that paieth tribute, insomuch, as people will but walke and refresh themselves under the shadow of it, must pay a custom therefore unto the people of Rome. Dionysius, King of Sicile, and the first of that name, caused them to be brought from Rheguim in Calabria to his roiall cittie, where his palace was, onely of a singularitie because they should be seen to give a shade before his house, where afterwards was made the Colledge or a place of public exercise."

and:

> "Of a certaine region we have before written, called Aulocrene, lying in the way between Apamia and Phrygia: and there the paisants of that countrey can show you that very plane tree, on which Marsyas the musician hung himselfe in a melancholly mood, for that he was overmatched in his owne cunning and professed skill, by Apollo: And surely like it is, that even then he made choice of that tree for the bignesse."

Evelyn says:

> "This beautiful and precious tree, originally sacred to Helena . . . was so doated on by Xerxes that Aelian"

and other authors tell us:

> "He made halt and stopped his prodigious army of seventeen hundred thousand soldiers, which even covered the sea, exhausted rivers, and thrust Mount Athos from the Continent, to admire the pulchritude and procerity of one of them; and become so fond of it, that, spoiling both himself, his concubines, and great persons of all their jewels, he covered it with gold, gems, necklaces, scarfs, and bracelets, and infinite riches; in sum, was so enamoured of it, that for some days neither the concernment of his grand expedition, nor interest of honour, nor the necessary motion of his portentious army, could persuade him from it."

Elwes and Henry in "Trees of Great Britain and Ireland" tell us that *Platanus orientalis* was introduced into England some time before 1562; the Western plane *P. occidentalis* in 1636; and distinction was made of the botanical species *P. acerifolia* in 1703. They also enumerate a great number of outstanding examples, including one "planted by Bishop Gunning in the Palace Gardens at Ely in 1896. It was found by the shadow to be about 100 feet high and 23 feet in girth at 3 feet from the ground". At Mottisfont Abbey there is a magnificent tree which Elwes measured in 1898, 29 ft. 8 in. at 4½ ft. from the ground. This tree is remarkable on account of its gnarled growth. He also mentions one at Woolbending Rectory, Sussex, about 105 ft. high by no less than 25 ft. in girth, and directs attention to the triumphant beauty of the avenue at Cowdray Park. They also say:

> "The planes in Berkeley Square are worth notice on account of their uniform burry trunks swelling at the base. . . . They were planted by Mr. Edward Bouverie in 1789 and are probably the oldest plane trees in London. According to Mr. Birkbeck the two largest, in 1906, girthed at 5 feet, 13 feet 10 inches and 13 feet 4 inches respectively, and were about 85 feet high. (The largest of these now measures 14 feet 9 inches in girth and 5 feet 1 inch in diameter at base.)
>
> Tradition says that this was a burial ground during the Plague of London in 1665."

Although these trees grow to a magnificent size in England they do not compare with those of which Pliny writes as follows:

> "and in truth this tree [the plane tree], and the situation thereof, is so admirable, that Licinius Mutianus, thrice Consul and late Lieutenant Generall and Governour of that Province, thought this thing worthie to be regarded as a memoriall to posteritie, when he and 18 *more persons* of his Companie used to dine and sup within the hollownesse of that tree; where the very leaves yeelded of the own sufficient bed and bench room to rest and repose themselves."

Record trees are also quoted in Greece, Constantinople, and Samarkand, where the immense girths of 37 ft. and 39 ft. were attained.

Earl Sandwich in the year 1739 directed attention to

> "the great Plane of the island Stanchio (anciently Cos). . . is remarkable for its size and the care with which the natives have attempted to preserve it. It has stood for time immemorial in the chief town of the island, and while it is the boast of the inhabitants, it is also, and with justice, the wonder of strangers."

He also remarked

> "Among the curiosities of this city is a Sycamore-tree, which is, without doubt, the largest in the known world . . . from the outside verge of which, to the trunk, I measured forty-five large paces."

It is supposed that early botanists mistook the *Acer pseudoplatanus* for the fig-tree, or gave it this name on account of its resemblance. It seems more likely, however, that the tree they saw was the plane tree. That which we call sycamore the Americans more correctly term the great maple. In bark and timber, in flower and seed, there is no resemblance whatever between the *Acer pseudoplatanus* and the *P. orientalis*. According to Sargent, Acer is the classic name of the maple tree, and Platanus is the name of the plane tree. In America all the timber of the Acer species is called maple, and that of the Platanus sycamore. In Scotland the produce of *Acer pseudoplatanus* is called plane. The resulting confusion can easily be understood.

Throughout France and Germany the value of the timber produced by the plane tree has always been recognized. Not only were the trunks of the trees utilized with the utmost economy, but even the limbs have been carefully converted and put to useful purpose for furniture, floorings, and interior decoration. In America, also, its value has been fully realized, and the wood has been quarter sawn, which displays handsome marking, and earned the name of 'lace-wood', by which it is well known to American craftsmen and in their export trade. It is only in England that the wood has been entirely wasted except as fuel.

The original oak panelling, comprising hall, staircase, and doors in a country mansion damaged in the course of the War of 1914–18 was replaced by American 'lace-wood', but while all who saw the woodwork admired it, not even the owner knew its name or origin.

Magnificent fully grown specimens of this particularly graceful tree can be found in abundance scattered throughout England, Scotland, and Wales, and roadside planting has been steadily carried out in all our towns and villages. In other directions, however, unfortunately, for more than a hundred years big-scale planting has been neglected.

SCIENCE AND THE WAR EFFORT

THE meetings on "Science and Victory" arranged by the Association of Scientific Workers in London on July 11, which took place simultaneously with one in Moscow, well emphasize the critical importance of science in the war effort of both nations and the determination of scientific workers to see that the fullest possible use is made of the scientific resources available. Copies of the addresses given have been made available by the Association.

Sir Robert Watson-Watt in his chairman's address put the essential point squarely enough: no military operation to-day can be a sustained success without applied science. Important and essential as are the other factors, without science they are not enough. Moreover, as other speakers pointed out, it is not merely the part of science in production, in the manufacture of munitions of all kinds and in the development of new weapons and of instruments of ever greater precision that is vital: a new scientific function—that of operational research—has emerged in Britain and in the United States, and in Soviet Russia appears to have existed before the outbreak of war.

Prof. J. D. Bernal's picture of these developments is highly suggestive. Operational research is no longer limited to the technical performance of weapons in the field under the supervision of those competent to assess performance and suggest effective improvements. Strategy as well as tactics has come under scientific surveillance on the field of battle itself. The processes of warfare itself, the effectiveness of various forms of attack and defence are being studied by specially trained men of science, and the results are being analysed and translated into improved tactical methods and weapons. In all this, Soviet Russia appears to have been a pioneer, though both countries are now using men of science for similar extended functions.

In Great Britain, at the present time, as Prof. Bernal suggests, the novelty of the military and operational use of scientific workers is attracting more attention and overshadowing some of the equally important achievements of science, no less vital to our war effort; in the fields of agriculture, nutrition and food supply, and health, it has provided substitutes for essential commodities of which we have been deprived or restricted by the War, especially in the Far East. The post-war consequences of these developments may well be highly important. It was natural for a meeting of scientific workers to look to establishing closer and more direct contact with Soviet scientific workers engaged with us in a common struggle, as has been done already with the United States, and to hope for similar collaboration in building up a new world in which science will at least be free to devote itself wholeheartedly to the service of humanity. Scientific liaison with the U.S.S.R. may well be an important aid to mutual understanding between the two nations, for if we have much to learn of the Soviet effort it is at least equally true that they have much to learn of Britain.

Prof. Bernal's review of these developments suggests, however, that an even more important post-war consequence may be a much greater general awareness of the importance of science: not merely an appreciation of its achievements but a greater desire to understand its method and possibilities. Mr. J. G. Crowther touched on this educational aspect, more particularly in respect of the opportunities in the munitions industry, in an address which referred to some points made at the British Association Conference last March on "Science and the Citizen" with regard to ways and means of increasing the public understanding and appreciation of science. None the less, the significance of the educational opportunities which the increased operational contacts with science in the Forces and the greater use of scientific instruments and weapons by fighting men themselves offer in respect of the post-war world, scarcely appears to be appreciated. If that opportunity is seized, if every possible means is used, whether now through such means as the Army Education Corps or through the Workers Educational Association and other instruments of adult education after the War, to bring home to the ordinary citizen not merely the achievements but also the nature of science and the limitations as well as the possibilities of the scientific method, we shall have taken a long step towards making it possible for society to enjoy the abundance which science has put within our power.

That achievement depends on the use of science, and our scientific resources for science—like planning—has its dangers and limitations, and Britain and Soviet Russia have much to learn from their widely different experiences. We cannot make full and wise use of science in a democracy without a widespread understanding of what science is, what it can do and what it cannot do, and in this respect it may well be that Britain lags somewhat behind Soviet Russia. What may fairly be open to doubt is, as Prof. Polanyi showed in a recent paper, whether Soviet Russia has always understood the true nature and limitation of the scientific method. Science and politics may be consorts but they are ill-mixers, and science and propaganda go ill together. Quality, not quantity, is the vital element in science.

The eloquent plea for co-operation and mutual understanding between science and government, statesmen and men of science, which was uttered by Mr. J. G. Crowther at the meeting emphasizes a further point which lies behind the effort of Soviet and British scientific workers in the struggle with Germany. Whatever the imperfections or neglect of science in Britain and in Russia, both countries are to-day struggling against a power which has struck at the well-springs of scientific thought and advance. As a cable from the Moscow meeting addressed to the Association stated, the Nazis have set themselves deliberately to extinguish the torch of knowledge. Their regime threatens the very existence of scientific life and thought, and while that threat remains there can be no security for the free spirit of inquiry, the patient, independent investigation and creative thought which are the essence of science and the secret of its advance. That challenge has been taken up wholeheartedly by British and by Soviet scientific workers, and the meetings in Moscow and in London on July 11 attest their sincerity and determination. Scientific workers, in addressing themselves to their wider tasks and in accepting wholeheartedly their social responsibilities, must remember also that it is their prime responsibility to guard and cherish that unfaltering quest for truth which is at the heart of science, and to make sure that in all their organization and planning they consent to nothing that impairs their freedom of inquiry or utterance and the ultimate but fundamental loyalty to truth.

CLINICAL PHOTOGRAPHY

AT a meeting of the Association for Scientific Photography held on September 18 at Middlesex Hospital, Dr. H. Mandiwall stressed the particular qualities required in clinical photography. In his opinion these are: (*a*) a simple straightforward record with perfect definition; (*b*) a self-explanatory picture, but nevertheless one which does not include unessential portions; (*c*) a well-presented print, as much care being taken in the mounting and finishing as in a studio portrait; (*d*) in the case of colour photographs, the colour must be true to the original. This is of particular importance in skin diseases which are characterized by the colours of the part affected. It was suggested that a Clinical Group should be formed in the Association, which would discuss the special aspects of this work, and compare technique.

Another point was the collaboration between photographers and manufacturers of apparatus. The requirements of clinical photography are in many cases distinct from those of studio or outdoor work, and it would be of great advantage to have certain apparatus specifically designed for the work.

In opening the meeting, Mr. T. Pomfret Kilner stressed the importance of standardization in technique, particularly in his own sphere of plastic surgery. The photographs taken before and after treatment must be strictly comparable as regards type of film, exposure, lighting, etc. He illustrated his remarks with views of a simple equipment employing a Leica camera and photoflood lighting which enables photographs to be taken at any angle and can also be used for copying radiographs or documents. He recommended that Ortho materials be used for the majority of work; previous to the War, he had always used Agfa Isochrom film.

Miss Hilda Marsden showed examples of the work done in clinical photography at the Christie Hospital, Manchester, using a half-plate camera with studio technique. She laid special stress on the importance of lighting, particularly in delineating the outlines of growths, etc.

In the discussion which followed the papers, Mr. J. E. Andrews showed illustrations of a convenient set-up for photographing patients in bed which was made with the aid of a pair of steps such as is always available in a hospital. The camera was fitted to the top of the steps with the usual ball-and-socket joint and could be directed in any required position. By means of interchangeable lenses and lights also fitted to the top of the steps at varying angles, he was able to take a variety of photographs of a patient from head only to full-length. He had found that a 4½-in. lens was adequate for full-length and an 8-in. for head and shoulders. A 14-in. lens gives a close-up of an individual part with the patient lying flat about 5 ft. below the camera.

As a matter of interest, Mr. Andrews showed a photograph of a patient with one brown eye and one blue, taken with orthochromatic film without a filter. Only one photoflood lamp was used, and the colour rendering was excellent.

Mr. K. Hennell (Metal Box Co.) said that he had taken several thousand clinical photographs during the War in colour, and used Sashalite bulbs exclusively for illumination. He considered this was the best method for tackling a variety of jobs and agreed with Mr. Kilner concerning the necessity for standardization. He exhibited several samples of colour prints on paper.

It was in the discussion generally agreed that clinical photography should be undertaken by a professional photographer who would find it advantageous to make a special study of physiology and anatomy. It was not considered reasonable to expect a medical man or surgeon to do his own routine photography, and it was also pointed out that the majority of hospitals, while equipped for X-ray work, are not well equipped for clinical photography.

Those interested in the formation of a Clinical Photography Section should write to the secretary of the Association, Mr. R. M. Weston, at Houndwood, Farley, Nr. Salisbury, Wilts.

REHABILITATION OF THE 'SCORCHED EARTH' IN THE U.S.S.R.

THE preliminary arrangements have recently been announced by the Soviet Government for the rehabilitation of the different regions of the U.S.S.R. as they are liberated from the Germans. A Commission has been set up representing forestry, timber supply and other interests to arrange for the erection of buildings on the collective farms and of dwellings for the workers. Use is to be made of local supplies of brick or artificial stone of various kinds, and of houses prefabricated in factories: the standard is to be a flat for four families, and thirteen factories are to be put into operation with a capacity of eighty flats per month. The Agricultural Bank will allow 10,000 roubles credit to each family for a period of seven years.

Railways also are to be restored, and dwellings for the staff and the various establishment shops and buildings are to be erected.

Such live-stock as were driven eastwards are to be restored, and regulations have been drawn up for the movement of specified numbers of the animals from seventeen of the reception areas to collective farms in specified regions including Orel, Smolensk, Voronezh, Stalingrad, Rostov, and Stavropol: impressive totals are involved, including 206,000 cattle, 342,000 sheep and goats and 53,000 horses, though these represent only a fraction of the peace-time numbers of animals in these regions. Collection of the animals at specified points in the reception areas was to be completed by September 1, and they were to reach their destination between October 1 and 15. The difficulties will be considerable, but the routes have been worked out: the journey for the animals is in some cases 800 miles. Arrangements have been made for feeding and watering the animals during their journey and for checking the numbers and duly accounting for their arrival. The risk of carrying disease will be very great, but fifty veterinary surgeons (1 for each 12,000 animals) and a hundred assistants are to be seconded from the reserve of the Red Army and distributed along the routes. In order to ensure further attention when the animals reach their destination, schools are to be set up in each liberated province giving veterinary courses varying in duration from three to twelve months. The Agricultural Publishing House is to be given 50 tons of paper for the printing of instructional literature. Other decrees deal with the provision, payment and transport of the drovers.

Collective farms are being recommended to keep all male calves of 1942 and 1943 to become working oxen.

In the case of poultry, it was necessary to establish incubator and poultry-breeding stations sufficient to deal with 16 million eggs: the aircraft industry was instructed to supply the thermostats and thermometers. The number of specialists required will be considerable: 130 are to be detailed for the new stations, but this number will not suffice, and it is proposed to start courses for training a further 580. In order to ease the work of the collective farms as they are re-established, considerable exemptions during the first year are permitted from the deliveries required to be made by the farm to the State; these apply to farms that have suffered from enemy occupation and households that have suffered bereavement or in which the able-bodied members belong to a specified group of experts. Tractor maintenance and repair stations are to be set up, and schedules are issued of spare parts, etc., that must be stocked.

Special provision is made for supplying railway workers with allotments of about one-third acre on which they may grow what crops they like. These plots are to be exempt from compulsory deliveries to the State: they are to be supplied with seeds, pigs and chickens. Provision is also to be made for the education of orphans and children of Red Army men and partisans; there are to be nine 'Suvorov' military schools, somewhat like the old cadet schools, each for about five hundred boys; and twelve 'industrial' schools for boys from the age of ten and for girls from the age of eleven. Co-education is not adopted in these new schools. Houses for 16,300 children are to be set up.

LIGHTNING PROTECTION OF BURIED CABLE

FOR the new toll facilities now being installed in the United States, much of the cable is laid underground to secure greater immunity from effects of sleet, snow, and storms. Burying the cable alone is not necessarily sufficient to free it from the effects of lightning damage. Moreover, when lightning damage such as fusing of cable pairs or holes in the sheath does occur, it is not so easy to locate and repair as on aerial cables since excavations may have to be made at a number of points. As a result of this situation, studies have been made of the factors affecting damage of buried cables by lightning, and the remedial measures which have been devised to provide substantial protection in most cases that are encountered are described in an article by E. D. Sunde (*Bell Lab. Rec.*, **21**, No. 9 ; May 1943).

When lightning strikes, the current spreads in all directions from the point where it enters the earth, and if a cable is in the vicinity it will provide a low-resistance path so that much of the current will flow to the cable and in both directions along its sheath to remote points. The flow of current in the earth between the lightning channel and the cable may give rise to such a large voltage drop that the breakdown voltage of the soil is exceeded, particularly when the earth resistivity is high. The lightning stroke will then arc directly to the cable from the point where it enters the earth, often at the base of a tree. When this happens practically all the current reaches the cable sheath. Furrows so long as 100 ft. have been found in the earth along the path of such arcs.

The current entering the sheath near the stroke point is attenuated as it flows toward remote points. The current leaving the sheath must flow through the adjacent soil, and the amount of this leakage current per unit length of cable is therefore smaller if the soil resistivity is high than if it is low ; thus the current will travel farther the larger the earth resistivity. The flow of current along the sheath produces a voltage between the sheath and the core conductors, which is largest at the stroke point. This voltage is substantially equal to the resistance drop in the sheath between the stroke point and a point which is sufficiently remote so that the sheath current is negligible. Since the higher the earth resistivity, the farther will the current travel, this resistance drop will also increase with the earth resistivity. The maximum voltage between sheath and core is thus proportional to the sheath resistance and also to the square root of the earth resistivity. Carrier cables now being used are of smaller size and have a higher sheath resistance than full-size voice-frequency cables, and for this reason they are more subject to lightning damage, particularly when the earth resistivity is high.

Tests were made on the Stevens Point-Minneapolis cable, using a surge generator which generates a short-time surge of current similar to that of a lightning discharge but of much smaller magnitude. An earth was established remote from the cable, and the surge generator was connected between this earth and the cable sheath, and between the remote earth and earths at distances of 10, 25, and 100 ft. from the cable. Results of the tests are given in the article.

When the voltage at the point where current enters the sheath is great enough to break down the insulation, the conductors and sheath are brought to essentially the same potential by the arcing. Under these conditions, the voltage between conductors and sheath increases with distance along the cable. A maximum is reached at some distance from the original fault, and beyond this point the voltage slowly decreases. After a puncture of the insulation where the current enters the sheath, other failures may therefore occur at some distance from this point in either or both directions. A single lightning stroke may thus cause insulation failures over a considerable distance along the cable.

One method of reducing failures caused by lightning strokes to buried cables is to increase the core insulation. This has been done for most new installations of buried cable. The cable itself, and such accessories as cable terminals and stubs, loading pots, and gas-alarm contactors are all provided with sufficient extra insulation to double the dielectric strength between cable conductors and sheath. For a cable like the one on which measurements were made, such increased insulation would reduce the number of lightning strokes that could cause failure by direct arcing to the sheath to about 15 per cent of the total instead of 50 per cent, and would almost entirely eliminate the danger of breakdown when lightning strikes the earth as much as one hundred feet from the cable. Another method, which may be employed in addition to the extra insulation where excessive lightning damage would otherwise be expected, is to bury shield wires over the cable. These conduct away part of the lightning current and thus reduce the amount that flows along the sheath. These wires may be ploughed in with the cable, or they may be installed afterward. The percentage of the current carried by the wires depends to a greater extent on their inductance relative to that of the sheath than on their resistance. Two wires are employed in order to obtain a lower inductance than would be possible with a single wire.

On the route between Stevens Point and Minneapolis where the shield wires were installed after the cable was in place, two 165-mil copper wires about 12 in. apart were ploughed in some 10 in. above the cable for a distance of 80 miles. Surge measurements made after these wires were installed indicated that the wires reduced the voltage between sheath and core conductors by about 60 per cent, which is in substantial agreement with theoretical expectations. The shield wires should thus reduce the number of direct lightning strokes that would be expected to cause failure to about 10 per cent, instead of 50 per cent without shield wires.

PLANT DISEASES

SEVERAL papers concerning plant diseases appear in a recent number of the *Transactions of the British Mycological Society* (26, Pts. 1 and 2 ; April 1943). Measurement of the intensity of plant disease in the field has occupied the attention of a sub-committee of the Society's plant pathology committee. The results indicate some rather suggestive lines of attack in the investigation of several diseases. A graph showing the incidence of potato blight at the Seale Hayne Agricultural College for different years, and for other localities for 1941, is very illuminating. The quick rise to a high degree of infection in 1932 is in marked contrast to the slow development of the disease in 1937, and merits further investigation. Other results are quite as suggestive. The sub-committee's main contribution, however, is in the standardization of methods, details of which are given in the paper.

W. C. Moore continues his series of descriptions of new and interesting plant pathogens. A disease of maize seedlings raised in nutrient solution was found to be caused by *Fusarium moniliforme*. It could be eliminated from the grain by soaking and heating to 54° C. for 20 min. A species of Penicillium, probably *P. hirsutum*, has also been assigned as the cause of a rot of Scilla bulbs, and *Helminthosporium Allii* is the pathogen of a bulb canker of garlic. This disease was discovered in an imported consignment before it could be planted, and so should not establish itself here. A brief note by H. Duerden announces the appearance of *Pythium mamillatum* in England. It produces a damping-off disease of cress, similar to that caused by *P. deBaryanum*. Elizabeth Blackwell gives details of the very complex life-history of *Phytophthora cactorum*, a species with pathogenicity upon such widely differing genera as Cereus, Acer, Pyrus, Pæonia, Rheum, Fagus, Pinus and others. The species is paragynous and homothallic, and considerable progress in control of this parasite should result from this careful analysis of the many stages of its life-cycle.

In the realm of bacterial plant pathogens, W. J. Dowson publishes a list of species, with synonyms, which should be included in the genera Pseudomonas, Xanthomonas and Bacterium. This should be useful as it is difficult for the general pathologist to follow all the changes in modern bacterial nomenclature.

FORTHCOMING EVENTS

Saturday, October 9

Sheffield Metallurgical Association (joint meeting with the Microchemical Section of the Society of Public Analysts and the South Yorkshire Section of the Royal Institute of Chemistry) (in the Department of Applied Science, The University, St. George's Square, Sheffield), at 2.30 p.m.—Symposium on "Microchemical Analysis".

Tuesday, October 12

Society of Chemical Industry (Chemical Engineering Group and London Section) and the Institution of Chemical Engineers (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 2.30 p.m.—The Rt. Hon. Lord McGowan: "The Future of the Chemical Industry".

Royal Society of Medicine (at 1 Wimpole Street, London, W.1), at 5 p.m.—Dr. W. Norwood East: "The State, the Criminal and the Psychiatrist".

Chemical Society (Leeds Area Local Section) (in the Chemistry Lecture Theatre, The University, Leeds), at 6.30 p.m.—Dr. E. H. Farmer: "Autoxidation in Relation to Olefinic Structure".

Thursday, October 14

Institute of Fuel (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 2.30 p.m.—Dr. E. S. Grumell: Melchett Lecture.

Friday, October 15

Physical Society (at the Royal Institution, Albemarle Street, Piccadilly, London, W.1), at 4.30 p.m.—The Rt. Hon. Lord Rayleigh, F.R.S: "Optical Topics, in part connected with Charles Parsons" (Eighth Parsons Memorial Lecture).

Royal Society of Medicine (at 1 Wimpole Street, London, W.1), at 4.45 p.m.—Dr. N. S. Finzi: "Impending New Developments in Radiotherapy".

Saturday, October 16

Institute of Physics (X-Ray Analysis Group) (joint meeting with the Manchester and District Branch) (in the Physics Department, The University, Oxford Road, Manchester), at 2.30 p.m.—Sir Lawrence Bragg, F.R.S.: "The Physical Optics of X-Ray Analysis": Short Papers and Exhibition of Apparatus, etc., relating to Industrial Problems.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Teacher of Chemistry for Junior Work in Technical Day School and Industrial and Intermediate B.Sc. Classes in the Technical College, a Teacher of Mathematics for Junior Work in Technical Day School and Technical and Intermediate B.Sc. Mathematics in the Technical College, and a Teacher of Mechanical Engineering Subjects up to Higher National Certificate standards, in the West Hartlepool Technical College—The Chief Education Officer, Education Offices, Park Road, West Hartlepool (October 14).

Teacher of Mathematics and Physics in the Junior Technical School and Senior Part-time Classes in the Batley Technical College—The Director of Education, Education Offices, Batley, Yorks. (October 15).

Advisory Officer in Plant Pathology—The Secretary, West of Scotland Agricultural College, 6 Blythswood Square, Glasgow (October 15).

Director of Robert Gordon's Technical College—The Secretary, Robert Gordon's Technical College, Aberdeen (October 16).

Borough Electrical Engineer—The Town Clerk, Council Offices, Kettering (October 22).

Professor of Engineering—The Registrar, University College, Singleton Park, Swansea (November 20).

Lecturer in Educational Psychology and Teaching Method—The Principal, Gipsy Hill Training College for Teachers of Young Children, at Bankfield, Bingley, Yorks.

Technical Assistant in a Government Department in London for work connected with the planning of production of X-Ray Equipment—The Ministry of Labour and National Service, Central (Technical and Scientific) Register, Section D.562, Alexandra House, Kingsway, London, W.C.2.

EDUCATIONAL RECONSTRUCTION (2)

Access to the Universities

SECTIONS VIII and IX of the White Paper on Educational Reconstruction deal with access to the universities and the recruitment and training of teachers respectively.

The common thread woven into each of these two sections is insistence on the quality of the human material which is involved. There can be no argument with the statements that "high ability [should not be] handicapped by the accidents of place of residence or lack of means in securing a university education" and that there will be required "a larger number of teachers of the right calibre", and there emerges, perhaps for the first time in proposals for educational legislation, a true and active appreciation of the worth of the job of teachers, and the necessity for a unified scheme for selecting and nurturing men and women for the teaching profession. Tribute is paid in the assertion that "it depends almost entirely upon the quality of those who staff the schools whether the reforms proposed will . . . , in practice, work out as real educational reforms". As we emphasized in the previous article (NATURE, October 9, p. 393), the child must be the true and only centre of education; nevertheless we must see to it that the teacher is trained in the best and fullest manner in order to qualify for the very important tasks before him.

Dangers lie in the administrative problems involved; a mere expansion of the numbers attending universities can be no solution of the problem of quality; machinery must be devised and tested over a period of years to ensure that only those of high ability or of outstanding personality, or a balanced combination of the two, secure places in our universities and university colleges, and that the delightful but uneconomic student who has in the past spent five and even ten years sampling the several faculties of a university (or even several universities) is no longer able to do so. The selection of university men and women is not easy, and it is by no means certain that we have evolved a satisfactory technique in the present scholarship examination system.

Changes are foreshadowed by the recommendations in the Norwood Report, which embody the idea of a school record carrying at least equal weight with formal examination as a test of fitness to profit by university education, and though much experiment will be necessary, there is here the basis for more equitable selection of those who are not academically brilliant, but who possess sterling character and have been brought up in homes where the very fact of being at home has been an education. Such men and women must not be lost to the universities. In the past many of them have not had access to universities because of the financial position of their parents, and might, on a stringent test of academic fitness alone, be ruled out absolutely.

Under the Government scheme of further education and training an influx of men and women whose further education has been prevented or interrupted by war service will do much for the social and communal life of the universities, which have recently suffered from a reduction in the average age of entry and length of stay of students, with the result that university staffs have rightly complained that many of their students are unable to profit by university methods of teaching, and need more guidance than the already hard-pressed tutor is capable of giving. The White Paper generously looks forward with confidence to the large demands upon the administrative and teaching staffs which will be made by this scheme, and it seems probable that the four-term year which has perforce been instituted in many universities will need to continue, for a time at least, in order to meet the needs of the scheme, even at some sacrifice of the invaluable leisure time which has been lost to war-time students.

Recruitment and Training of Teachers

Greater problems, both legislative and administrative, lie in the proposals for reform in the recruitment and training of teachers. Both recruitment and training are so much and so obviously in need of reform that much has been published on the subject, in almost every type of journal: so much that it can confidently be asserted that the McNair Committee, whose report is awaited with interest, will achieve a miracle if it makes any proposals which can be regarded as original.

The implication that systematic provision should be made for boys and girls to continue their education after senior school age, and afterwards prepare for the teaching profession "if at, say, 15 years of age they express a desire to do so", is dependent for its successful working on a very generous scale of financial assistance, and absolute freedom for the individual to contract out of teaching if he wishes. This means recognition that the training of a teacher up to almost any stage before his active employment in a school is a worth-while investment for the country, even if he never enters the teaching profession, and the complete abandonment of the present system whereby secondary school boys and girls may be tied by agreement to teach after their further education and training at the expense of the State in university or college. Too often the present scheme of Board of Education grants is used as a means to the end of getting a 'college education' for the academically sound student who may be temperamentally quite unsuited to teach, and under whom the next generation of pupils must suffer; nor may the discovery of temperamental unsuitability be made until the fourth year at a university. It is very satisfactory that the White Paper records the fact that "War has revealed that the ability and the character required of teachers is not to be found exclusively in the boys and girls in the grammar schools". Too little respect has been paid to the very great value of the work of men and women in the Armed Forces who have, often for the first time, found themselves called upon to be teachers—teachers not only of matters military but also of current affairs and citizenship, as in the Army Education Directorate's A.B.C.A. and British Way and Purpose schemes—and exemplars of the virtues of courage, constancy and good-fellowship which are none the less virtues of the teacher than of the sailor, the soldier and the airman.

The introduction into the teaching service of men and women who have served in the Forces or in industry will provide a nucleus of teachers who "have had experience of life other than as students and teachers". The narrow circle of school, training college and school must be broken down whatever the cost in administrative labour and cash. In this connexion any plans for a period of public service between leaving school and entering the training colleges or universities will be welcome, as a start in the right direction. Thereafter, exchange between schools, industry and commerce, and public service must be facilitated by every possible means. Great goodwill will be necessary, and recognition by industry, for example, on one hand, that teachers can serve them usefully in employment, and education authorities, on the other hand, that recruits from industry are valuable. Linking the two are those whose talents lie in youth service and adult education respectively.

Much has been done to break down the narrow traditions of the 'two-year' training colleges, which have in the past been responsible for cramping the natural initiative and love of adventure of their students. In this respect the denominational colleges have been the greatest sinners, and in fact are still not free from blame; they have seldom shown the virility of the 'municipal' training colleges. How is it to be ensured that they are more broad in their outlook than heretofore? As mentioned above, a period of public service would do much to ensure that the entrants to such colleges themselves demand a broad and liberal training. The development of the training colleges' association with the universities must provide the basis for a happier state of affairs. Such association already exists in the joint committees of training colleges and universities which are centred in most of the 'provincial' universities. These joint committees, although substantially similar in constitution, having university and training college representatives, vary considerably in their nature, since in certain cases both university and training college representatives are also members of the local education authorities of the area in which university and training colleges are situated. A committee so constituted cannot be expected to favour the full partnership which denominational colleges must be encouraged to enter. It is to be hoped that the McNair Committee will favour the reconstitution of joint committees to include persons of standing, perhaps co-opted, whose main interest is the furtherance of the view that training teachers is *one* problem, and that the university interest is merged with that of the training colleges to the advantage of both. Perhaps the day is not far off when student teachers will receive all their training—academic and professional—within the universities themselves, thus giving them a broader outlook by working in collaboration with students of other callings.

EDUCATION AND RESEARCH IN AERONAUTICS

THERE have been many happenings lately that have tended to focus attention upon the subject the facilities that should be provided in the post-ar future to obtain training for the various branches the profession of aeronautics. The applied side of is science, the design, construction, and maintence of both fighting service and civil aircraft and gines, the handling of air transport services, and e host of auxiliaries called into being by these, will ed a great deal of pioneer work, based on original inking, for its organization. The advances in the chnical outlook made during this War, together th the problems inseparable from the great increase the size of the industry, compared with its pre-war nensions, bring into much prominence the question training the personnel for the profession.

Many facets of this problem are purely educational d are thus inevitably bound up with the proposals the reform of the educational system of Great itain, as foreshadowed by the White Paper on ducational Reconstruction" presented to Parliant by the President of the Board of Education, d the Norwood Committee's report on "Curriculum l Examinations in Secondary Schools". Follow- this there are aspects that are general to all those nches of applied science that for convenience can called engineering. The Institutions of Civil gineers, Mechanical Engineers, and the Institute Physics have each issued memoranda upon these. llowing this, the particular side of the subject that aeronautical was the subject of a discussion at etings of the Royal Aeronautical Society, a report n which is to be published in due course. The th report of the Select Committee on National penditure, on aircraft production, also throws uable light upon the requirements in technical sonnel of the aircraft industry as a whole, and nments upon the inadequacy of the supply at sent.

The subject of professional education in aeronautics eculiar in that it is of more recent birth than most the other professions, and consequently is in a te of immaturity. Most of those intimately conted with it consider that it is suffering from malrition, a view supported by the Select Committee's ort. The possible remedies are of three kinds. expansion of the present system, the same expann with the addition of teaching covering what e consider to be gaps in the existing scheme, or a plete and radical change in the method of apach. Of these the second is the most generally oured—indeed it appears to be the only one sible. The first is admitted, by experience, to be ufficient, and the last, for fundamental reasons, is possible in any educational scheme. Within these ndaries there are two outlooks, training in scien- and technical work, and craftsmanship. These cannot be separated entirely; indeed, it is from craftsman that some classes of technical men uld be recruited.

During the period between the two world wars, steady if not spectacular progress was made in the organizing of training in aeronautics in Great Britain. The many authorities concerned have worked together, and consequently there is functioning to-day a properly co-ordinated scheme that caters for all types of trainees, and is inter-related sufficiently to allow an ambitious candidate to climb the technical ladder to the highest rung if he is mentally capable of doing it. Financially, the position is not yet good. There are a few scholarships devoted specifically to aeronautical training, and many firms in the industry have schemes for helping their apprentices in this respect. The cost of obtaining a part-time training in the technical side of the work, being mostly in the hands of the rate-aided local technical institutions, is not prohibitive to the average apprentice. Under the present war conditions, a small proportion of the State bursaries have been awarded for the study of aeronautical engineering, and the Royal Air Force has a scheme for allowing certain selected technical personnel to study aeronautics, following syllabuses that are of general aeronautical outlook rather than peculiar to Royal Air Force requirements.

The training facilities available in Great Britain at present can be roughly summarized into groups covering the types of trainee envisaged. Repair and maintenance mechanics who are licensed by the Air Ministry, known as 'ground engineers' or 'licensed aircraft engineers', have to pass examinations in certain theoretical aspects of their work. The manufacturing firms, sometimes in conjunction with the local educational authorities, hold classes of this kind. The craftsmen who actually build the firm's products are distinct from these repair men, and do not necessarily hold ground engineer certificates. Their training is of rather a broader outlook and is catered for by the City and Guilds of London Institute (Technological Department), which holds an annual examination called "Aeronautical Engineering Practice". Classes for this are held by the local technical institutions. Apprentices needing a more theoretical training can enter for either national certificates sponsored by the Board of Education and the Institution of Mechanical Engineers, external university degrees, or the associate fellowship of the Royal Aeronautical Society, taking such aeronautical subjects as are available in the curriculum at their teaching institution. Some employers allow their apprentices to undertake some form of sandwich system of training, under which they can give sufficient time to theoretical study in their local institution to be considered as full-time students. They then enter for national diplomas or internal degrees, with similar aeronautical subjects. Some entrants prefer to enter upon a full-time course of study direct from school, and leave their practical training until they have obtained their theoretical qualification. They will take similar courses for either national diplomas or university degrees. There is a certain advantage in this latter system in that if a student finds that he has a flair for the more scientific work, and does not wish to take up the engineering side, he can pass on to study for the higher branches of scientific research without spending his time in a works. The advisability of ignoring the applied side of any science is open to question, but there may be some aspects of aeronautical science, the more mathematical, for example, where an intimate knowledge of the engineering work is not so important. Lastly, there is postgraduate study available for either of the foregoing men who desire to take up the more scientific work and feel that they would profit by a year or more extra study of the particular aspect of the profession that appeals to them. Such students will probably take up either research or the more responsible posts in design or industrial organization.

This is the programme of training as available at the present time, but there is a school of thought that holds the view that there is one serious gap in this. They consider that advanced postgraduate study at a university is academic in character, and while it is correct for the scientific man and research worker, it is not near enough to the applied side for the industrial entrant. They ask for a postgraduate institution of a more practical character, where much of the teaching would be given by visiting lecturers who are actually practising in their profession, and possibly where flying also could be done at the same time. Such flying would, of course, be looked at from the point of view of being supplementary to the technical training being given, and for the development of the technique of flying and its various auxiliary services, rather than the mere mechanical handling of an aircraft. This view was propounded by Sir B. Melvill Jones at a recent meeting of the Royal Aeronautical Society, and it is understood that it is held by a special panel of the Aeronautical Research Committee which is investigating the question of training in aeronautics for the Government.

The problem that has now to be faced in the world of aeronautical training is two-fold. First, it is necessary to consider the present system, that has been functioning to a gradually increasing extent since 1919, and to use the post-war reconstruction period to correct its shortcomings, if any, at the same time allowing for a substantial increase in the size of the industry as compared with 1938, before the commencement of the present War. Such alterations may be necessary both in size and quality. Secondly, it is necessary to organize the practical side of the industrial training, apprenticeship, etc., in such a way that it accommodates itself both to the new conditions in the general educational scheme, and the improved theoretical aeronautical training facilities that will be available consequent upon this enlargement. There will also be an interim problem of dealing with the younger people who have developed an interest in aeronautics by reason of their war-time work, either in the services or industry, and wish to make it their profession. They will have received a partial training in the practical side of the work—probably a specialized but narrow one due to the war-time necessity of becoming expert in one job only—and will need a rather special training to enlarge this and add the theoretical outlook in as short a time as is reasonable.

To come to concrete proposals, the existing scheme is fundamentally correct, and, possibly with t addition of the proposed more practical postgradua school, adequately covers the ground. At present fails to bring forward sufficient trained men on because it is not used to its fullest extent. Th failure is difficult to explain, but it is none the le very real. To those working behind the scenes aeronautics, the fact that there were insufficie well-trained persons coming along has been obvio for many years. The sources of supply can be divid roughly into two parts, the apprentice and the fu time, mostly university, man. The apprentices a taken on in works generally according to numbe agreed upon with the appropriate trades unions, a are presumably sufficient to maintain the supply new craftsmen. Most of these appear to start some form of theoretical study under schem arranged by the employers, but only a woefully sm number of them ever reach the stage of taking a of the qualifications that stamp them as being of u for the professional side of aeronautical work. T full-time students' case is different, but the resu are equally disappointing. Aeronautics deman fundamental training in the underlying subjects a then adds training in the application of them to own work. This postulates a longer and m arduous training, which only a few seem to have t ability, enthusiasm, and financial resources to co plete. Somehow this source of recruitment to t more technical side of the work must be increas Fundamentally, the matter would probably set itself in time if the conditions in the profession w made more attractive; but in the meantime so propaganda would seem to be necessary to rou sufficient enthusiasm in the minds of the younger m who will be entering their training period in t immediate future. An increase in the number institutions offering classes in aeronautics would h the general situation, and in this case such edu tional authorities might be expected to display vis in their programmes, and offer such facilities ev though it is not yet established that there exists a lo demand for them. Consultations with the lo A.T.C. organization might prove a fruitful sou of recruitment for the more elementary classes least.

The failure of so many apprentices to 'stay t course' on the theoretical side indicates that employ might do more to rouse their enthusiasm, and th possibly a certain proportion of the apprenticesh available should be reserved for boys whose sch records mark them as being of the more studious ty A proper apprentice supervisor, with the corr outlook and the necessary authority, should be a to watch his charges and possibly allow the m likely ones to give a progressively increasing amo of their time to their technical studies, as they be to show that they are likely to be of more use in t work than with their hands.

The problem of those returning from the Force national service in industry will be as thorny a as it was after the War of 1914–18, but there is fact that is outstanding as a result of our experie then. Selection of men to take up the theoret ide of aeronautics must be made with great dis-rimination. A mere interest in the subject, by eason of having done war work of a practical nature n it, is not enough. The special knowledge demanded by the aeronautical profession is not easy to ssimilate, and if it has to be done in an intensive ourse, the difficulties will be even greater. A revious interest in aeronautics added to a good war-ime record in it is almost a *sine qua non*. School ualifications sufficient to be able to understand the ork is necessary, but enthusiasm for the profession f aeronautics is equally essential for the hard task hat they are undertaking. The man who merely akes up a university course as a way of obtaining living for the immediate future will always be a roblem to the teaching world. That he should be llowed to fill a place in the scheme for higher training n aeronautics, which will be strained to its utmost imit, is unthinkable.

THE ADVANCED THEORY OF STATISTICS

he Advanced Theory of Statistics
y Maurice G. Kendall. Vol. 1. Pp. xii+457.
London: Charles Griffin and Co., Ltd., 1943.)
2s. net.

THIS very handsomely produced volume is one which it will be a pleasure to any mathematical tatistician to possess. Mr. Kendall is indeed to be ongratulated on the energy and unswerving per-everance needed to complete his heavy task, and ncouraged in the still unflagging energy which will e needed for the second volume. So far as he has arried his work, he has certainly done something to ustain the credit of Great Britain in mathematical cholarship.

In his preface, the author explains that his original ntention had been to write in co-operation with four ther distinguished statisticians. In the event we must congratulate ourselves on the fortunate fact hat the intervention of the War compelled him to arry the work out on his own plan, and without the upport and encumbrance of such collaboration.

On the many occasions on which I have been onsulted as to the feasibility and desirability of a arge-scale work on mathematical statistics, I have ointed to the discouraging circumstance that the dvances of recent decades had been so subversive, ot only to the methods but also to the points of iew from which statistical problems are approached, hat any presentation containing material expected y, and acceptable to, the leading minds of an earlier eneration would come soon to be recognized as ointless and obsolete. Mr. Kendall deals tactfully ith this difficulty, though without altogether solving t. Thus at first sight his contents pay at least formal espect to the old convention of expounding statistical methods under the headings, measures of central endency, measures of dispersion, and finally, crown-ng the arch, measures of correlation. The last four f the sixteen chapters in this volume are indeed iven up to various coefficients of correlation and ssociation, not, it is true, quite in the old style, for he subjects are treated with a mathematical com-etence, based on a wide familiarity with the litera-ure, far beyond anything previously attempted, but one is tempted to say also, beyond the intrinsic interest or practical utility of the methods under discussion. Why should anyone now wish to calculate a rank correlation, or a coefficient of contingency ?

The modern reader, on the other hand, would like to see a much fuller development of Chapter 10, on exact sampling distributions, and a far wider and more varied exposition of the uses of the χ^2 distribution than is supplied in Chapter 12. In the case of both these chapters, the subjects of which are of the greatest importance to the statistical reader, the approach is barred by an opening section of quite unnecessarily complex algebra. The perfunctory treatment of χ^2 suggests that Mr. Kendall is not immune from the weakness of other heavily burdened authors to scamp those portions of the work in which they are not particularly interested.

The same perfunctory attitude emerges on p. 59 in a short section devoted to the calculation of factorial moments by successive summation. The author says : "The use of the method in practice lies in the fact that for certain calculating machines the progressive summation is easier to carry out than the processes involved in the method of Example 3.1".

From one very highly equipped machinist to another, this may be true enough, though surely an understatement, for a method which replaces a large number of multiplications by an equal number of additions. The saving of labour is evidently most important when no machine is used at all, a condition in which even the most perfectly equipped among us must occasionally work. The method also of abbreviating the process further by summing from both ends to a chosen origin is not given, so that, unless he has independent information, the reader is not in a position to judge how valuable the procedure really is.

The presentation of purely mathematical points is, generally speaking, careful, although, as has already been suggested, cumbrous proofs are sometimes used just where, for the general usefulness of the book, they should have been avoided. Two small points and one of greater importance are perhaps worthy of the author's attention with a view to subsequent editions.

To say, as on p. 53, that "The moment about the mean of order $2r$, if it exists, is given by" a certain expression is not logically the same as to say that it is defined by the expression, and therefore exists, if the expression has a meaning. Kendall's form of statement suggests, contrary I suppose to his intention, that there is some other condition necessary for the existence of the moment.

In examples 3.7 (p. 59) and 3.8 (p. 66) the symbols μ and κ appropriate to the population are applied to statistics derived from a sample. It is true that the sample is large, giving the heights of more than eight thousand men, and therefore the errors of random sampling will be comparatively small, but it is none the less a pity to confuse the student at this stage by blurring a distinction which will later require his full attention. The other examples, 3.9–3.11, are properly applied to distributions.

Mr. Kendall is much interested in the rather formidable algebra of the symmetric functions used in mathematical statistics. Thus the formulæ for translating moments into cumulants and *vice versa* are set out in full to the tenth degree on pp. 61–64, and in other parts of the book a good deal of space is given to proofs establishing similar relationships. In my own experience the approach to all work of this kind is greatly eased for the majority of mathematical statisticians by a preliminary consideration of the nature of partitions, and an introduction to the appropriate terminology and notation. Whereas, however, in Chapter 3, on moments and cumulants, mention of partitions seems to be carefully avoided, the reader of Chapter 11, in which more comprehensive methods of analysis are developed, is confronted without warning or preparation with the notions (*a*) of partitions, (*b*) of partitions of multipartite numbers, and (*c*) of separations of partitions, as ideas which are essential to each difficult stage of the argument. The fact is that some mathematical statisticians have thought about partitions and in terms of partitional notation, while others have not done so at all. These are not going to be helped, but only baffled by the manner in which the ideas are here introduced.

Each chapter is followed by a series of exercises, some of which are exceedingly good. Some examples in the text are at least equally difficult to the reader anxious to understand the solution. Thus in example 7.2, the following argument is used to demonstrate the recurrence formula, which yields very prettily the series of sub-factorials developed by Euler for the problem of the game of *Rencontre*: "Suppose that u_n is the number of ways in which all the letters go wrong. Consider any two letters. If these occupy each other's envelopes, the number of ways in which the remaining $n-2$ letters can go wrong is u_{n-2}; and there are $(n-1)$ ways in which two letters can be interchanged. But if one letter occupies another's place and not vice versa, which can happen in $(n-1)$ ways, there are u_{n-1} ways in which the others can go wrong". I have not made the test widely, but I submit that very few mathematicians unfamiliar with this particular argument would be able from this form of statement to see where the two factors $(n-1)$ really come from.

R. A. FISHER.

ORE DEPOSITS

Ore Deposits as related to Structural Features

Prepared under the direction of the Committee on Processes of Ore Deposition of the Division of Geology and Geography of the National Research Council, Washington, D.C. Edited by W. H. Newhouse. Pp. xi + 280. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1942.) 44*s*. net.

THE study of the genesis of ore deposits does not appeal to geologists in Great Britain (with a few notable exceptions) to anything like the same extent it does in the United States and Canada. In America a great and growing number of men have adopted economic geology applied to mining as a profession, and interesting contributions to the science regularly appear in the scientific and technical press. The reason may be due to greater interest shown in mining ventures by people in America, or may result from greater opportunities for practising the profession provided by the many diverse types of deposits found there.

In any event, the rapid expansion of the non-ferrous mining industry in the United States has stimulated the scientific study of the deposits themselves. In a few outstanding cases, such as manganese in the Gold Coast and coal in Kent, the geologist either actually discovered or predicted the presence of the mineral, but in the majority of instances 'finds' by prospectors have created the need for geological specialists to interpret the discoveries.

Some decades ago, geologists in Great Britai paid more attention to the problems of the meta mining engineer, but with the decline of non-ferro metalliferous mining the interest of the majorit waned. This is unfortunate because, while it is tru that most of the easily accessible deposits have bee worked out, there exist several areas which, if tho oughly explored, might again yield discoveries whic could be worked successfully in spite of worl competition.

This book, which is published by the Princeto University Press and prepared under the directio of the Committee on Processes of Ore Deposition o the Division of Geology and Geography of th National Research Council, Washington, and i edited by Prof. W. H. Newhouse of the Massachusett Institute of Technology, can be divided into tw parts. The first portion consists of a general discussion on the controlling effects of structural feature on the deposition of various ores, while the secon and major part contains short discussions by som sixty different contributors on particular ore deposits to illustrate the diverse effects of variou geological features. The studies do not enable an hard and fast rules or laws to be promulgated, bu the deposits do fall within a broad classification.

Mining geology is not yet, and probably never wil be, an exact science, because there are too man exceptions to general rules; but a careful study o this work will afford guidance to many a geologis when confronted with a difficult problem concernin a particular deposit, and it is therefore recommende as a valuable book of reference which should b included in every library of scientific books.

The book is very well illustrated and the prin easy to read, but it is too bulky to form part of field library. As is only to be expected with a volum containing contributions by so many America writers, the ordinary reader who has been so unfortunate as not to have received some of his training i America will find difficulty in translating some of th scientific or technical terms used into those wit which he is more familiar.

J. A. S. RITSON.

DEMONSTRATION-LECTURES IN PHYSICS

Analytical Experimental Physics

By Prof. Harvey Brace Lemon and Prof. Michae Ference, Jr. Pp. xvi + 584. (Chicago: University o Chicago Press; London: Cambridge Universit Press, 1943.)

THE purpose of this book, as stated in the preface is to provide a record of demonstration-lecture which were given to second-year students attending general course of physical sciences at the Universit of Chicago. Will it fit any British syllabus? A comparison with those of the University of Londo will be a stage towards deciding this question. Th book contains what is needed for London Intermediate Science, and much more besides. Of th twenty questions set in the London External Genera B.Sc. in June 1938, seven can be answered fully wit the aid of this book, seven partly; and on th remaining six it gives no guidance. The deficiencies for this purpose, are mostly that useful genera notions are not developed in sufficient quantitativ detail. For examples: (i) pairs of separated thi lenses are treated, but not by the method of principal points; (ii) the potential energy of an electrostatic system is worked out for two conductors, but not for many; (iii) a formula for the bending of a beam is stated without proof; (iv) it is assumed that the gravitational attraction of the earth for all bodies near or far acts as if the mass of the earth were all concentrated at its centre. Electromagnetic waves receive scant attention. Yet in other directions the book goes far, treating, for example, the gyroscope, the mass-spectrograph, the three-colour analysis of vision, and the triode-amplifier; but not the triode-generator. The reviewer is left wondering to what extent syllabuses in Britain and the United States are determined by scientific or social necessity, and to what extent by academic habit.

The outstanding merit of the book resides in its illustrations. There are 584 line diagrams in the text. In addition, there are 64 pages, called plates, showing photographs accompanied by descriptions. Many of these photographs are taken from cinematograph records so as to exhibit the successive phases of lecture-experiments. From these sequences the student can obtain a much more vivid impression of what actually occurred than he could from a single line diagram; but, to gain this advantage, he will probably have to make an extra effort; for the photographs inevitably show many features that are not essential to the principle of the experiment and which must be sorted out mentally. Also some essential marks are almost, or quite, invisible in the print, notably the clock-hand in several dynamical experiments. Perhaps a bright hand on a black face would have photographed better. The defect is, however, repaired by printing the clock-readings. Many of the plates are superb.

The text flows along interestingly. The discoverers, of many nationalities, are mentioned with their dates, and with allusion to the more important controversies. There are exercises for the student both in calculation and in thinking out what would happen if the experimental conditions were varied. Thus the book affords that training in method and criticism the absence of which was lamented in a recent review ("Shortened Physics", NATURE, July 3, p. 7). But, with these merits, the work of Lemon and Ference could not be short. It weighs 2·3 kgm.; and inquiry of the English publishers elicits a provisional price of 42*s*.

The descriptive text is interspersed with mathematical proofs of the usual kind, employing the calculus sparingly. There is an appendix of 16 pages on pure mathematics, partly an explanation, partly a summary of useful but unproved formulæ.

There is an unfortunate muddle about the paraboloidal mirror. If we ignore diffraction, then all the rays from an infinitely distant point which are reflected by the mirror meet again in a common point-image, provided the object-point lies on the axis of the paraboloid, but not otherwise. As the object moves off the axis its image becomes increasingly blurred. Lemon and Ference call the image "aplanatic" (p. 482). But that is contrary to the usage of Abbe, who discovered the sine condition for aplanaticism, by which he meant the sharpness of the image both on and off the axis.

Detailed criticism must not hinder the recognition of the general excellence of this book by Profs. Lemon and Ference. It will be of particular value to any students who are unable to attend demonstration-lectures. LEWIS F. RICHARDSON.

PETROLOGY OF IGNEOUS ROCKS

Eruptive Rocks

Their Genesis, Composition, Classification and their relation to Ore-Deposits; with a Chapter on Meteorites. By Dr. S. James Shand. Revised second edition. Pp. xvi+444+3 plates. (London: Thomas Murby and Co. Ltd.; New York: John Wiley and Sons, Inc., 1943.) 25*s*. net.

THIS second edition of Prof. Shand's valuable text-book has been fully revised, partly rewritten and rearranged, and enlarged by 84 pages. The sequence of chapters is much the same as in the first edition, although their contents have been to some extent redistributed, but new chapters on the order of crystallization, compatible and incompatible phases, and eruptive rock complexes, have been inserted into the petrological part of the book. The chapter on eruptive ore deposits which formed part of the first edition has been omitted.

The result of this revision and rearrangement is that what was originally a good account of the physical chemistry and origin of igneous rocks is now perhaps the best in print. However, in the chapter on temperature and pressure in the magma, there seems to be some confusion between magmatic reservoir temperatures and temperatures of intrusion or extrusion. The conclusion on magmatic temperature (p. 69), that there is no evidence that any body of deep magma ever had a temperature higher than 1170° C., and that, in many cases, the temperature may not have exceeded 870° C., may be correct in regard to intrusion or extrusion temperatures. But in view of H. H. Thomas's work on the xenoliths occurring in basaltic sills of the Loch Scridain district (Mull), the new minerals in which imply reservoir temperatures of between 1400° C. and 1250° C. *before* intrusion, the above conclusions cannot be maintained with regard to reservoir temperatures.

Prof. Shand's powerful strictures on the Rosenbuschian order of crystallization, and on the vague uses of the ill-defined term "magmatic differentiation", will now probably be subscribed to by the majority of petrographers.

The second half of the book deals with classification, nomenclature, and description, and in this Prof. Shand excels. Something might be said in criticism of the mode of classification, which is based, as the author says, on antipathies rather than affinities between the igneous rocks, but much more space than is here available would be needed for its adequate discussion. The classification is simple, easily understandable, easily applied, economical of names, and will thus appeal strongly to the student. Researchers, however, will turn with grateful enthusiasm to the wealth of excellent digests of recent work on igneous petrography, which are drawn from the petrographical literature of the whole world, not even excluding the Soviet Union.

The book is clearly and simply written with many exciting passages in Prof. Shand's well-known pungent, not to say pugnacious, style. The chapters are headed by apposite quotations which testify to his wide humanistic reading, and end with well-selected and unhackneyed lists of literature. Although it does not consider some important aspects of igneous rocks as, for example, their distributional and tectonic relationships, the book is, in the reviewer's opinion, by far the most complete and satisfying text now available to put into the hands of the advanced student of the subject. G. W. TYRRELL.

TIME PERSPECTIVES IN SCIENCE*

By Prof. A. E. HEATH

University College, Swansea

ONE of the best ways of broadening our minds, and clearing ourselves of local limitations and prejudices, is travel in space. Travel in time is equally effective, and cheaper. It takes us out of our narrow setting and restores our sense of proportion by confronting our parochialisms with those of other peoples and periods.

This is true in science as in other human concerns. Here, too, are fashions and unconscious temporal shortsightedness. Even inside the special sciences themselves, historical considerations are important. Although "any science which hesitates to forget its history is lost", it can equally be asserted that any science which does not relate itself to its historical background runs the risk of sterility. Its origins, as specialization increases, may be lost sight of; and dead ends appear in developing thought as in the evolution of living creatures. Its connexions with cognate studies tend to be overlooked, and fruitful possibilities of investigation, produced by a sort of cross-fertilization, neglected. The very meaning of its terms may be too narrowly conceived, as Huxley hinted when he said, "The parallax of time helps us to the true position of scientific conceptions as the parallax of space to that of a star".

It is, however, when we think of science as an instrument for furthering human ends that the full importance of its history comes to light. Viewed in its wider setting, we can see that man has, now, accumulated more knowledge than he can apply. This is sometimes spoken of as a failure in moral insight. If that were the correct diagnosis it would be a very curious thing, considering the many centuries of concentration by saints and sages on moral issues. I prefer to put the emphasis elsewhere. I should call it a failure of nerve. Wisdom is not knowledge only, but knowledge plus plasticity. We lose our nerve when we fail to adapt ourselves to change.

It is not commonly realized how modern the modern temper is. By applying a balanced form of reflexion (in which a passion for brute fact is combined with capacity for generalization) to every department of human life, we have achieved, in the last three centuries, a picture of the world which is staggeringly different from those cosmologies within the framework of which our institutions have been built. The step from Dante's world to that of Einstein and Freud has been taken much too briskly for us to keep pace. The new world is just as wonderful as the old, providing the fullest scope for philosopher, poet and prophet to work their synthesizing genius upon. But this enterprise has scarcely yet begun. We have been too much occupied with piecemeal adjustments to the disturbing political and economic developments which have followed on the heels of intellectual change. Consequently we have been forced to carry over our old mental furniture (to amplify an image of the late J. W. N. Sullivan's) into new settings for which it is ill-suited. Our first dwelling, at the beginning of this period of three hundred years, was the neat, cosy, friendly world of Dante in which we could live confidently; regarding Nature as subservient to our human purposes and destiny. From that we passed on to the wider world, big and orderly but detached, of the Newtonian system; and now, in our own day, we are translated to a vast, though bounded, universe—so bare and empty that the mind reels at its immensities and cold unconcern. Throughout all these changes we have carried with us the same homely mental furniture that served us in our first dwelling-place. It is as though we began by making shift with the contents of a small cottage when we moved into a lordly mansion in Park Lane. That would be bad enough. But the further move is like transplanting our little belongings to the middle of Salisbury Plain.

It is hard enough for us to readjust our attitude to the world outside us—to the macrocosm: but when we turn our attention inwards to the microcosm, to the little world of man and his social relationships, the difficulties increase enormously. For in this realm, too, we are carrying into the new era, with even greater tenacity, mental presuppositions about all sorts of things—about nationality, about economic realities, about sex and family—which served us in the past but may now, in altered conditions, bring ruin upon us. It is not a question of destroying our mental furniture: we cannot hope to start afresh with new minds and bodies. Our problem is, rather, how best to reshape and supplement what we already have. But before such refashioning can be begun, we have to rid ourselves of the superstitious terrors which now hinder us, in every department of social affairs, from organizing our civilization so as best to

* Substance of a lecture at the British Social Hygiene Council Summer School at Eton College, August 1943.

serve the ends of human happiness. Scientific knowledge does not of itself free us. "Learning", as Santayana has remarked, "does not liberate men from superstition when their souls are cowed and perplexed". To the bread of knowledge must be added the salt of intelligence—by which I mean the power of plastic adjustment to change. That is the touchstone by which the future of man on this planet can be gauged, as it has been the test for every other animal throughout geological time: Can he adapt himself quickly enough to changes in his environing conditions ?

Our social and cultural disharmonies are thus largely the product of our failing to acclimatize ourselves to modern cosmologies. There is a disastrous divorce between what we know and what we feel : and to this our nerveless grasp upon our destiny is due. The prime essential for adaptation is a synthesis of the sciences of life with the sciences of the physical world. We shall need to fit our studies into a wider and more inclusive perspective. If we are to have a technocratic order it must transcend its engineering stage and become a biotechnocracy.

In the achievement of this, historical considerations are paramount, and they need not be complicated. We have the knowledge. It only needs to be effectively geared. Even such ordinary things as chronological charts provide admirable means of travel through time. These have two useful qualities. They help us, in the first place, to grasp the connexion between events in a given period ; and in the second place, to set the period itself in its proper time-relation to others.

As an example of the first, there is reproduced in Fig. 1 a small portion of a long chronological chart I made partly for my own amusement and partly because I wanted to get an idea of the historical background of scientific work in different ages. I therefore put down the names of men of science and their discoveries, varying the size of the lettering with the importance of the man or his work, in red script : and then entered on the chart, in black, events in social and cultural history. I was astonished to find how illuminating a bare chronological series of events, set out in this way on a uniform time-scale, could be. In the portion of the chart here illustrated it is possible, for example, to see at a glance that the seventeenth century was not merely the age of mechanics in its narrow sense ; that characteristic is reflected also in other branches of human activity. Besides the names of Newton and Leibniz we see that of Borelli, whose book "De Motu Animalium" is the first application of mechanical ideas to the structure of the human body ; of Spinoza, whose "Ethics" was written, under the influence of the prevailing mood of the time, in "a geometrical manner" ; of Scarlatti, who did not scorn technical experiment as a basis for composition. The whole thing hangs together.

The complete chart, upon which the sixteenth century is also entered, is several yards long, and can be moved on its rollers so that it can be looked over in a few minutes. History unrolled in this manner, by the yard, enables us to catch other unities. It becomes clear, for example, that each age has its own peculiar scientific flavour. Thus there is a certain disconnectedness in the scientific entries in the sixteenth century : it was more like the spasmodic inventiveness which still stands for 'science' in many minds. When we turn to the seventeenth century, we notice at once instances of interconnexion and co-operation. Results in one field were used in another—as when Galileo, hearing of the invention of the telescope, constructed one, but turned it immediately to astronomical use ; or when Pascal tried the effect of carrying the Torricellian tube up a mountain to see if the lessened weight of the atmosphere would be registered. The increasingly co-operative and cumulative character of science in the seventeenth century was brought out also by the appearance on the chart of the date of foundation of all the great European academies of science. This characteristic makes one realize, as nothing else can, the importance of this century for future ages ; since without it the ground could not have been cleared of the age-long accumulation of systems which cumbered it. Individual men working in isolation could not have coped with the enormous labour of putting such systems to the test of fact.

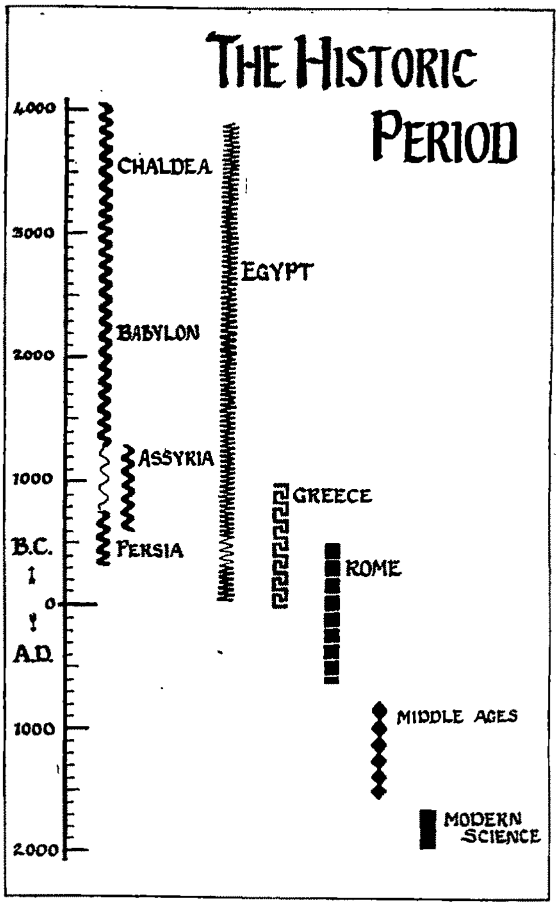

Fig. 2.

Another way in which the mere setting of events in order provided illumination was in the chart of the same kind which I made for the Middle Ages, and from which it became clear that the only scientific work in the earlier centuries of this period was under Arabic names. My own school-history had given me no hint of the fact that for several centuries the torch of Western civilization was in Mohammedan hands. Here, suddenly, I was brought face to face with it. The scraps of knowledge I possessed about the beautiful, but mysteriously early, Moorish architecture in Spain ; about Toledo steel ; about the Arabic origin of words like alchemy and algebra ; about the sources of our knowledge of classical antiquity in Arabic translations—all these fell together like the parts of a jig-saw puzzle. It was in this fashion that the detailed charts of the beginnings of modern science brought out unsuspected relationships between events and gave them new significance.

The second use of chronological charts, I said earlier, is to throw any given period taken as a whole into its wider relationships with others. For this the construction of time-lines is invaluable. If we wish, for example, to see how the modern period is related in time to the ancient world, and to the great empires which came before, we can represent them by a series of parallel lines, drawn to a common scale on a single chart. An example is shown in Fig. 2. Here is the picture of the brief period of modern scientific thought set in relation to its forerunners. It was fashionable some years ago in philosophical circles to talk about the bankruptcy of science. All that is necessary in reply is to take a reassuring glance at this chart; the balanced objective method of reflexion which we call science is too recent an acquisition for us to pass final judgment on it. It is interesting to notice, on this chart, the comparatively great length of line representing the stable early empires. It reminds us of the important fact that man has been able to build for himself solid, and even partially urban (though unprogressive), civilizations, on the basis of a rigid fibre of law—unchanging as the laws of the Medes and Persians—in which the subordination of the individual to society is far greater than in our time. Perhaps man was more docile in earlier ages, before his reflective awakening to complete social self-consciousness in ancient Greece. In our day we are forced to stress the character of *change*, because we live in a time of change and have much leeway to make up. But we must never forget that there have been many civilizations before our own; and that some of these, as in China and the East, can reach a high cultural level of an unchanging kind if they are content to remain mainly agricultural. For living renewal, cultural changes are necessary: but they must be viewed as biological processes: not like the mechanical changing of the harness of a horse, but more like a reptile shedding its skin: a delicate business, not lightly undertaken. A new biotechnology, in making this explicit, will help to free us from the exaggerated fears which tempt us to purchase security at the price of servitude.

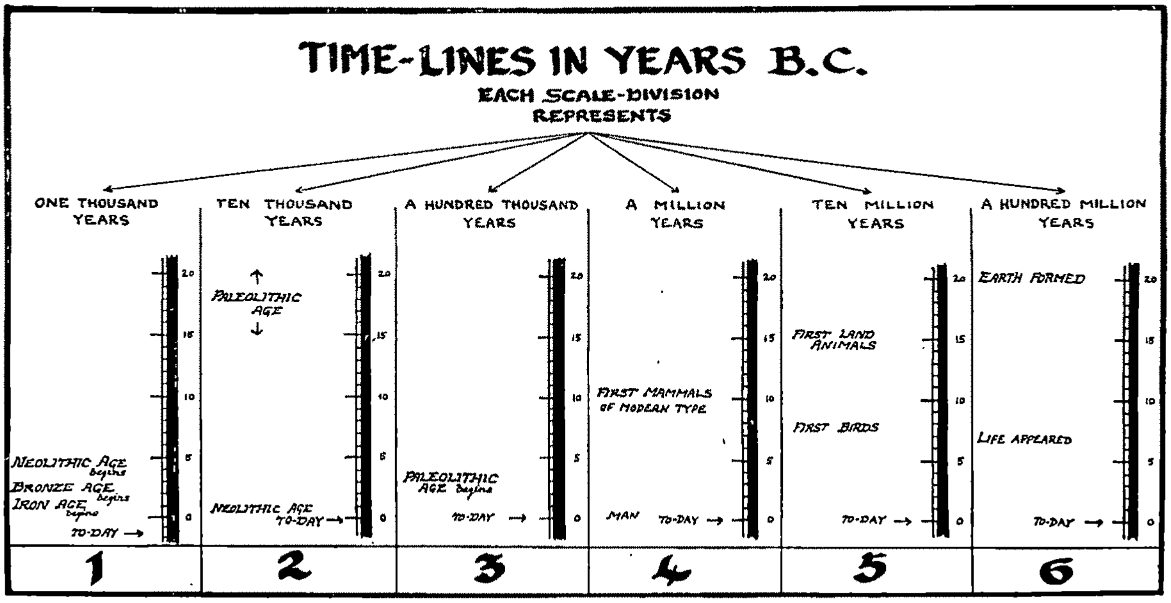

Fig. 3.

Even broader relationships of our modern period to earlier ages can be illustrated if we extend the range of our charts by making the scale successively smaller, a method used with great effect by Olaf Stapledon in one of his books. A series of time-lines constructed in this way is shown in Fig. 3. In the first of these, in which each unit of length represents a thousand years, we see the whole historical period dwarfed to insignificance in comparison with the range of man's neolithic civilization. In No. 2, where each unit is ten thousand years, this in turn is dwarfed by the vast length of the palæolithic or old stone age of man, before he had created anything but the crudest of stone weapons or developed an agricultural society. The palæolithic period indeed runs over to No. 3. We are thus enabled to comprehend the vitally important time-relation between man's hunting, agricultural and modern forms of social organization. It probably took him a quarter of a million years to create a society out of the hunting pack; and some five thousand years more to produce an ordered agricultural community. Building on his newly acquired powers over natural forces it should, Prof. J. B. S. Haldane has not too hopefully suggested, take him a shorter time to evolve a stable industrial society. Perhaps we shall be more hopeful if we remind ourselves how brief, in comparison with his whole life, is the modern period. If, now, we extend our scales still further we have on No. 4 the appearance of mammals of modern type; on No. 5 birds and the first land animals; and on No. 6 there comes at last into our ken the beginning of the earth itself.

But the beginnings of things remind us inevitably of ends. Our imagination, once started, may range forward into the far distant future: and we may pass beyond these discussions of the immediate problems of human civilization to wonder about their ultimate end in the death of the solar system.

We have been looking at man in the light of time. It may be felt that the tale is incomplete unless we also try, with Spinoza, to view him "in the light of eternity". Many will be able to face this last ordeal hopefully because they are convinced that, whatever may be the final fate of our world, there is an eternal place for man in the universe. I myself have no such conviction. Yet I do not despair—as some unhappy folk do, who have not the support of faith. To them I would offer the consolation of another journey through time under the guidance of Sir James Jeans. Imagine a clock which ticks not seconds but years. Its minutes will be a man's three score years. By this clock it was only seventy years ago that the earth was formed; only three days since man appeared; and only five minutes from the beginnings of balanced reflection. *On this scale* the astronomer gives man, at a very low estimate, another seventy years to run his course upon this planet. Mankind is thus, by this reckoning, a three-days old baby, born into a house seventy years old. He has only in the last few minutes woken up to a first awareness of his surroundings, and has the prospect of seventy years of life before him. There are moments in the lives of men, even of young men, when they fret at the passing of time. Like the Shropshire Lad contemplating the loveliness of cherry-blossom in spring, they murmur regretfully: "Of my three score years and ten, Twenty will not come again". But it is only a passing mood at twenty. It should not be a mood at all for the new-born infant.

There is another lesson to be learned from this way of viewing the human race in time. The baby is not likely to be concerned at the briefness of its life: but it is, so modern psychologists tell us, likely to be longing inarticulately for a return to the simpler conditions of dependence which it enjoyed before birth. That mood, so beautifully expressed in another of A. E. Housman's poems beginning, "Be still my soul, be still; the arms you bear are brittle", can carry forward into later life. Our infantilisms in social affairs bear witness to this. The danger which faces the human race in its present infant form is not hopelessness at the prospect of ultimate extinction, but despair at the harsh complexities of life which t is being forced to face. The real choice before us is between despairing refusal to grow up and its only alternative—resolute advance to maturity along the path of clear-eyed reflection.

STUDIES OF TWINS IN THE SOCIAL SCIENCES

By JOAN C. SQUIRES

TWINS, together with other multiple human births, have always been of interest to the society of which they are members. In primitive communiies, twins are regarded as being possessed of supernatural powers, which may or may not prove propitious to the group. Within the last seventy years, social scientists have made use of twins in an effort to solve the vexed question of the respective influences f heredity and environment on the formation of human character and physique.

There are two distinct types of twins. Dizygotic r fraternal twins are the product of two separately fertilized ova, which are independent from the moment of conception. Twins of this type have a common pre-natal and post-natal environment, but apart from these similarities, the latter enhanced by the fact that they are of the same age and thus subject to common experience, they appear to bear no more resemblance to one another than to other siblings. They may be of the same or opposite sex. On the other hand, monozygotic or identical twins are the product of one ovum, which, after fertilization, splits into two—these twins possess the same genetic constitution and are always of the same sex. Criteria for diagnosing monozygotic twins include a striking similarity in general appearance, which results in their being mistaken for one another, such as the possession of identical hair colour and texture, eye colour and pigment pattern on the iris—and a stronger cross than internal resemblance in most of the details of the finger and palm patterns—that is, the right hand of one twin resembles more closely the right hand of the other than his own left hand. It must be made clear that the term 'identical' can, in one respect, be misleading, since, as Prof. Newman points out, no two persons are born exactly alike—but he attributes the slight physical differences of monozygotic twins at birth to the inferior pre-natal position of one to the other, and the consequent decrease in blood supply[1]. The principle that all men are born equal is a political belief rather than a biological truth. The fact, however, that identical twins have the same genetic constitution, while fraternal twins differ in this respect within the limitations of the parental genes, makes the problem of heredity-environment influence easier to solve, since by series of control experiments the approximate values of these two factors can be ascertained.

Francis Galton was the first person to make a study of this problem. He examined thirty-five pairs of similar and twenty pairs of dissimilar twins, with the object of determining whether or not similar twins became unlike as a result of difference in environment, and whether dissimilar twins became more alike when living in the same environment. The segregation into similar and dissimilar was not as scientific as it would be were the experiment carried out to-day, but it approximated roughly to a division between identical and fraternal twins. Galton relied for his evidence on reports of the twins made by near relations or friends. These anecdotal sources of information have now been rejected in favour of control experiments. He was concerned more with a study of the physical than the mental characteristics. Both members of seven pairs of similar twins suffered from the same physical ailment, and there were two cases of similar insanity. Eleven pairs reported similarity in association of ideas—for example, one twin would begin a sentence and the other would end it. In nineteen cases of similar twins, however, there were marked differences in disposition, but these were ultimately attributable to illness or accident. This led Galton to the conclusion that: "we may, therefore, broadly conclude that the only circumstances within the range of those by which persons of similar conditions of life are affected, that is, capable of producing a marked effect on the character of adults, is illness or some accident which causes physical infirmity. The impression that all this leaves on the mind is one of some wonder whether nurture can do anything at all beyond give instruction in professional training. There is no escape from the conclusion that nature prevails enormously over nurture, when the differences of nurture do not exceed what is commonly to be found among persons of the same rank of society and in the same country."[2]

Galton's conclusions formed the basis of the heredity school of thought, whose views were accepted without question for some years. At the beginning of this century, however, men of science began to resume experiments with twins to test the validity of Galton's arguments. The first study of twins to make use of tests was that of Thorndike in 1905[3]. Thorndike wished to discover whether twins are more alike in abilities subject to training than in those not subject to training. With this purpose in mind he constructed tests which would measure educational achievement and those which would measure mental ability, unaffected by training, from the fact that there was no higher correlation between the attainment of twins in the educational achievement tests than in those measuring purely mental ability. Thorndike deduced that the similarity of twins was inherited rather than acquired, particularly as the correlations between twins of an older age were slightly less than those of younger twins. In this experiment there was no attempt made to distinguish between identical and fraternal twins.

Modern intelligence tests were first used with twins by Merriman in 1924[4]. He divided the twins into two age-groups—the 5–9 years old and the 10–16 years old. His results concerning the resemblance at a younger and older age tallied with those of Thorndike. He found, also, a higher correlation between twins of like sex. As one of the criteria for diagnosing monozygotic twins is that they are always of the same sex, this confirmed the fact that identical are more alike than fraternal twins. Having studied the handwriting of twins and found it not very similar, he put forward the suggestion that the similarity in growth and structure, which is found to obtain between many pairs of twins, may not necessarily extend to the finer organization of the nervous system.

Intelligence testing of twins has led to interesting results. Merriman discovered that twenty-five out of sixty-seven pairs of like-sex twins had identical intelligence quotients, and that the measurements of siblings resembled those of fraternal rather than of identical twins. Wingfield discovered that the intelligence quotient correlation between identical twins was 0·90, while that between fraternal twins was 0·70. Working with forty-two pairs of monozygotic and fifty-seven pairs of dizygotic twins, his results showed that the intelligence quotient correlation between the former was almost twice as great as that of the latter. His conclusions state, among other things, that differences in intelligence are closely related with differences in relationship, and are doubtless due to hereditary differences, but this does not mean that the intelligence quotient is not modifiable by training[5]. Hogben, who conducted experiments along the same line, discovered that the mean difference in intelligence quotient between identical twins was 9·2, while the difference in the case of fraternal was 17·8. He also made the interesting discovery that on re-testing, an identical twin resembles his co-twin more than himself, as shown by the previous test[6]. Identical heredity does not abolish intellectual differences, but it does reduce them to negligible proportions. Research in this direction has proved the idea that twins are sub-normal to be a fallacy. A person suffers from no intellectual handicap by being one of a pair of twins.

Rosanoff studied more than a thousand pairs of twins, in which one or both exhibited some kind of mental disorder, and his conclusions are of interest[7]. Reports showed that only about half the cases of mental deficiency were hereditary—the others were due to infantile diseases or birth injuries. Hereditary factors play a more prominent part in simple uncomplicated cases of mental disorder than in those associated with infantile palsy, epilepsy, behaviour difficulties and juvenile delinquency. They are also more important in the more extreme grades of mental deficiency, such as imbecility and idiocy, than in those grades commonly described as 'dull' or 'slightly subnormal'. Birth injuries are responsible for a large proportion of the latter class. Mental deficiency is more common in identical than fraternal twins, in males than in females, and in the first-born than the second-born twin. These conclusions showed that geneticists are faced with great difficulties when interpreting the pedigrees of families in which feeblemindedness is prevalent, since, as it has been shown, not all cases of mental deficiency are hereditary.

In the United States, a study of twins has recently been completed by a statistician, a psychologist, and a research worker specializing in the biology of twins[8]. The general purpose of the study was to discover the extent to which the characteristics of human beings, especially ability and behaviour, are determined by their genetic constitution, and the extent to which these characteristics are influenced by conditions of environment. In order to do this, they compared individuals who had been brought up together, but who differed in genetic constitution, that is, fraternal twins, with identical twins in similar environments, and followed this by a comparison of individuals who were genetically similar, that is, identical twins, but who had been subjected to different environments. The results of the former study showed that in the traits measured, that is, physical dimensions and intelligence, there was a higher correlation between identical and fraternal twins[9], leading to the assumption that genetic constitution is a large factor in these characteristics. Identical twins become neither more nor less alike as they grow older, but with age fraternal twins differ often in mental traits. It has been mentioned before that one member of a pair of identical twins may be born slightly inferior to the other; this initial difference may produce habitual difference—for example, it may be usual for one twin to take the lead in social intercourse. By a simple comparison of the differences in correlation between the two types of twins it was discovered that physical characteristics are least affected by environment, which has most influence on educational achievement and personality.

It was, at first, difficult to obtain suitable subjects for experiments with separated identical twins, since each of the pairs had to have been separated in infancy, and have been separated for a number of years, for the study to have any true value. Finally, the authors were able to publish reports on the cases of ten pairs of twins who had been separated in infancy, ranging from a few weeks to eighteen months old, and had been brought up in different environments for at least ten years. Small differences in environment were found to have little effect, as there were only negligible differences between the twins who had been brought up separately, but in somewhat similar environments. Whenever educational experience had differed to a marked extent, the twin with the greater amount of educational experience had a distinctly higher score on all ability and scholastic achievement tests. Where there was no or little difference in education, the scores of the separated twins tended to be as similar as those of identical twins reared together. For example, in one case, where one twin ceased her education at an early age, while the other went on to higher education and ultimately became a teacher, there was a difference of twenty-four points in intelligence quotient, in favour of the latter[10]. In another case, in which one twin had been educated at a village school, while the other had been educated at a modern school in a large city, there was a thirty-four months difference in mental age[11].

To digress from this specific study for one moment: a suggestion has been put forward by two Americans that an endowed school should be established in New York for identical twin pupils, staffed by identical twin teachers. In each grade there should be two classes, each containing one of a pair of twins, and each class should be taught by one of a pair of twin teachers. In this way, valuable work could be done in determining the best ways of teaching children. For example, one class could be taught French grammar, with no conversation, while the other could concentrate on speaking French ignoring any emphasis on grammar. Possessing the same genetic constitutions, the members of the two classes would have the same mental endowments, and therefore the difference in the ultimate result would demonstrate the value of one method as opposed to the other.

To return to the study of separated twins, the investigators state that the measurable difference in separated twins attributable to environment is, generally, equal to the sum difference in these cases plus an undetermined amount corresponding to that portion of the difference in unseparated cases attributable to environment. In weight and educational achievements, the separated twins were as different as average fraternal twins, but very similar in other traits. It can be seen that these two characteristics can be explained by the influence of environment. A marked difference in personality was found to be coupled with a marked difference in environment. For example, of one pair it was said: "These brothers, although brought up in widely different circumstances, are similar in manner and the measurable features of behaviour. However, their conduct, from the point of view of direction and social significance, differs widely. We might expect them to act with equal vigour, decision and persistence, but one to a socially constructive, and the other to a socially destructive end."

The following conclusions were drawn from this study. Every trait or character should be studied separately, for each involves different shares of hereditary and environmental factors. Physical characteristics are, in general, more influenced by heredity than mental traits; but the influence of heredity on mental ability is greater than on educational achievement.

A few years ago, Johannes Lange made a study of twins with the view of discovering whether or not the tendency towards criminal behaviour is predetermined[12]. He studied the case-histories of thirty pairs of twins, thirteen monozygotic and seventeen dizygotic, of which one or both had criminal records. Of the thirteen identical pairs, in ten cases both members had been convicted of crime—and in two of the other cases one member had suffered previously from a head injury, which may very possibly have accounted for the difference in behaviour. Of the seventeen pairs of fraternal twins there were only two cases in which both members were convicted criminals. The environmental factors were similar for fraternal and identical twins, but while there was extensive concordance in crime among the latter, there was little among the former. This was shown in the case of one pair of identical twins, both of whom were professional thieves and burglars, although they lived apart, and had had little contact with one another since youth. In his use of the twin method of study, Lange started with the assumption that if the hereditary make-up had no importance, then a comparison between identical and fraternal twins would show little difference; and lack of agreement between twins with identical heredity would enable the investigator to estimate the importance of environmental incentives to crime; and if twins with a different heredity showed closer agreement than other sibs, then environmental influences were important. Lange discovered that so far as crime is concerned, identical twins, on the whole, act in a definitely similar manner, while fraternal twins behave quite differently. Therefore, so far as the causes of crime are concerned, innate tendencies play a preponderant part, and similarity of environment does not entail similarity of behaviour on the part of fraternal twins. Heredity has a role of paramount importance; as well as exhibiting the same criminal tendencies, identical twins were found, in most cases, to follow the same patterns of behaviour in court and in prison. In one case, although in separate prisons and at different times, both twins were exceedingly troublesome and quarrelsome while undergoing sentence, showing strong paranoic tendencies. In identical twins, differences in criminal record were, for the most part, traceable to physical injuries. Social factors and those of experience can be relegated to a minor place in influence, but this does not mean that they can be discounted. Environmental factors are important to the criminal because of his suggestibility, but it is interesting to note, since environment itself depends to a very considerable extent on the type of individual concerned, that in no case did either or both members of the thirteen pairs of monozygotic twins move permanently into a different social class, whereas this did occur among the dizygotic twins, where, in one case, one twin was a Government official, while the other was a common vagrant and professional thief. We may, therefore, conclude that an underlying cause of habitual criminality is the inheritance of a predisposition to anti-social behaviour—certain hereditary dispositions are almost inevitably fated to express themselves in some form of criminal behaviour.

The results of the work of Prof. Kranz in the same sphere of research support Lange's heredity theory. The criminal records of the thirty pairs of identical twins, whom he studied, showed great concordance, while those of the forty-three pairs of fraternal twins showed concordance generally only in the fact that both twins had been convicted, not necessarily of the same crime or for the same number of times. Kranz considered that mere conviction record was not enough, since one twin may easily escape conviction. He surmounted this difficulty by a method of personal interview, which often revealed that in discordant identical twins the career of the non-convicted twin was such as to suggest a criminalistic character essentially similar to that of his convicted co-twin. He divided criminals into two types: the biologically inferior, who were chronic offenders, and those who had been led to one mis-step by unfortunate environmental circumstances: and he stated further that only the fate of the former type was predetermined by heredity.

From the results of these various studies of twins, which have helped and are helping to solve the problem of what Galton called Nature versus nurture, it can be seen that no simple answer can be given. The functions and values of heredity and environment are completely interwoven, and are not, as has been asserted by some people, intrinsically antagonistic. They vary in relative importance in regard to specific and general traits; but it can be said that, while both heredity and environment contribute to intelligence and the physical qualities of an individual, the contribution of heredity is several times that of environment. Education and training vary in relative importance in relation to the hereditary type with which they are dealing; the more intelligent the individual, the more potent the educational and general environmental influence. Environment tends to become more important as heredity becomes higher and more complicated.

Plato said that "Environment is most effective when it operates on complex nature". The forms of behaviour which constitute the adjustment of the individual to his environment at a complex level of performance are affected both by the original nature of the individual and by his environment and are not the sole product of either.

OBITUARIES

Sir James Morton

SIR JAMES MORTON, who died at the age of seventy-six at Dalton Hall, Carlisle, on August 22, represented in his own person the happy combination of dye-user and dye-maker that has played so large a part in the renaissance of the dyestuffs industry in Great Britain since 1914.

Sir James was the second son of the late Mr. Alexander Morton of Gowan Bank, Darvel, Ayrshire, and was educated at the village school of Darvel and at Ayr Academy. He became the chairman of Morton Sundour Fabrics, Ltd., Carlisle, and the Standfast Dyers and Printers, Ltd., Lancaster, and a delegate director of the Dyestuffs Group of Imperial Chemical Industries, Ltd.

His attention was first directed to the problem of fabrics fast to light when he went to Carlisle in 1920 with a branch of the Ayrshire works which had been manufacturing furnishing fabrics for some thirty or forty years. The story of the development which led to the founding of the Morton Sundour Fabrics Ltd., from his first experimental exposures conducted in his greenhouse at Penrith at that time, has been graphically told by him in his monograph "Fast Dyeing and Dyes". However slight its claims as a serious historical study, this brochure illustrates to the full the energy, enthusiasm and determination which were such important factors in his success and for which he will long be remembered. His exposures at Penrith and his continental journeys led him ultimately to a range of colours which on certain types of fabrics could be guaranteed against fading from sunlight or ordinary washing. This position was reached in the summer of 1904, and in the autumn of that year guaranteed goods were first announced and sold by Messrs. Liberty in London, for which the trade mark 'Sundour' was afterwards invented. A chemical side to the business for these new developments in dyeing was then started at Carlisle, and by 1914 the Sundour factory had become the largest side of the business.

Sir James' continued interest in the dyeing side of the business is shown by a number of patents he took out in the post-war years, but the cessation of supplies of fast vat dyes, particularly of the indanthrene colours, at the outbreak of war in 1914, led him to take up the manufacture of these dyes himself. He thought that by manufacturing a blue and a yellow, by reverting to some of the dyes used in his first fast dyes, it would be possible to maintain a limited range of Sundour goods. He succeeded in tracing the synthesis of indanthrene blue and yellow far enough to find that both were derived from 2-aminoanthraquinone, which is itself obtained from sodium anthraquinone-2-sulphonate or the silver salt, an intermediate product in the manufacture of alizarin. The determination with which he pursued this objective, overcoming not merely the chemical difficulties of the syntheses but also those presented by plant and raw materials, in the course of which he founded Solway Dyes, Ltd., and later Scottish Dyes, Ltd., was largely responsible for the award to him in 1929 of the Faraday Centennial Medal on the recommendation of the Royal Society, the Royal Society of Arts and the Royal Institution "for signal service rendered to chemical science and industry in this country by developing and extending manufacture of anthracene dyes and more recently by extending their application to silk and wool". In 1929 he was also awarded the Medal of the Royal Society of Arts for his lecture on "Fast Dyeing and Dyes" already mentioned. This and his address on dyes and textiles in Britain (1930) given at the British Association meeting at Bristol in September of that year, like his monograph "To Young Weavers", find a fitting place in the literature of the dyestuffs industry.

Morton was knighted in June 1936 for his services to the dye and colour industries. He was a member of the Dyestuffs Industry Development Committee during 1921-34 and of the Committee on New Industrial Development, 1931-32. He was awarded the honorary degree of LL.D. by the University of St. Andrews in 1930 and was a fellow of the Royal Society of Edinburgh as well as an associate of the Manchester College of Technology.

He took a close interest in social welfare work connected with his Company, and in starting the branch at Carlisle bought Murrell Hill House and its grounds as a place of recreation for his workpeople. He took a close interest in the Territorial Army and in the earlier Volunteers, and during the War of 1914–18 was actively concerned in the organization and supervision of munitions-making in the Carlisle area. He had made a close study of native textiles of many countries, of which he had a valuable private collection, and was proud of the fact that he was himself a weaver and a master of that ancient craft.

R. BRIGHTMAN.

Mrs. Arthur Strong, C.B.E.

MANY visitors to Rome, as well as colleagues and friends in Great Britain, will miss the wide learning, generous disposal of it, and impressive presence of the former assistant director of the British School of Archæology in Rome, Mrs. Arthur Strong, whose death in Rome on September 16 has been reported. Eugénie Sellers was brought up in France, and obtained honours in the Classical Tripos at Cambridge, from Girton College. In the intervals of travel in Germany, Italy and Greece, she gave university extension lectures on Greek sculpture, and conducted classes in the British Museum. In 1892 she published an excellent translation of Schuchhardt's "Schliemann's Excavations" brought up to date by an epilogue from Walter Leaf. Coming under the influence of Furtwängler, she translated also his "Meisterwerke der griechischen Plastik" (1895), a more ambitious and difficult task; and with her friend, Miss Jex Blake, she published a translation and useful commentary on Pliny's chapters on ancient art (1896). Her marriage in 1897 to the orientalist, S. Arthur Strong, librarian of the House of Lords, gave her access to the great British sculpture galleries, and on his early death in 1904 she succeeded him as librarian of Chatsworth and made valuable use of the collections there, especially the gems and the archæological drawings. During these years her tastes and judgment were maturing in a revision of current opinions about the relation of Roman art to Greek. As before, she found congenial utterance first in her translation of Wickhoff's "Roman Art" (1900) but later in her own "Roman Sculpture from Augustus to Constantine" (1908), the main positions in which she restated and illustrated in her chapters on "Roman Art" in the "Cambridge Ancient History".

Mrs. Strong had long been accustomed to spend much time in Rome, and was a valued helper in the early days of the British School of Archæology there. Under the directorship of Henry Stuart Jones (1903–5) the School undertook, as a collaborated task, a "Catalogue of the Sculpture" in the public collections of the city, which she knew so well, and she took an active part in the preparation of it. In 1909, when Thomas Ashby became director, Mrs. Strong was appointed assistant director, and held office until 1925. It was a strong combination, for while both knew Rome and Italy intimately, it was from quite different points of view: both were inspiring teachers and given to hospitality; the School attracted students, and prospered. Unfortunately, the war years 1914–18 broke up the genial society of archæologists; Ashby went to war duty, Mrs. Strong found other use for her abilities. But the chance discovery in 1917 of a subterranean basilica outside the Porta Maggiore gave her in its beautiful relief decoration a new text for her teaching about Roman art, and for her growing appreciation of the symbolic aspect of ancient art in general, expressed, for example, in her lectures and eventual volume on "Apotheosis and After Life" (1916). She had already given Norton Lectures on this subject in American universities (1913).

In due course Mrs. Strong resumed her place at the British School, produced an Italian revision of her "Roman Sculpture" (1923) and delivered Rhind Lectures at Edinburgh on Roman painting (1920).

When the British School was reorganized in 1925, Mrs. Strong retired from active work in it, and in 1928 completed a comprehensive survey of Roman art to the age of Justinian (1928). In 1927 she was made a C.B.E.; and she held a life fellowship at Girton College founded for her by her friends. Still living in Rome, she maintained and extended her wide circle of friends; making most generous use of her learning and practical knowledge of Italy, and in spite of increasing disabilities, continuing her literary activity almost to the end.

JOHN L. MYRES.

Mr. H. C. Lawlor

ARCHÆOLOGY in Northern Ireland has lost a prominent figure by the death, on September 4, of Henry Cairnes Lawlor, one of the many amateur workers to whom archæological studies owe so much. This is especially true of Ulster, since unlike the National University of Eire, the Queen's University of Belfast, of which Mr. Lawlor was made an honorary M.A. in 1924, provides no instruction in prehistoric archæology.

While most amateur enthusiasts in this extremely rich province were content to amass large collections of antiquities, Mr. Lawlor showed his interest and made his chief contribution by initiating a series of excavations which were to open up many new lines of research. He was by instinct genealogist and historian rather than prehistorian, and his excavations were conducted before the refinements of modern stratigraphical methods and the significance of minutiæ had penetrated to Ulster, but his was the first cultivation of a field of research which was to blossom notably in the decade ending in 1940. His best-known excavations were those at the pre-Norman monastic site of Nendrum in Strangford Lough, but he examined many other sites in Counties Antrim and Down, ranging in date from the megalithic period to the later Middle Ages. His most original work lay in the elucidation of those most puzzling and widespread of Irish field antiquities, ring-forts and souterrains, and in the study of the earthworks of the early Anglo-Norman period.

Mr. Lawlor published many excavation reports and memoirs, several pamphlets on local history, and a more popular general account of "Ulster: Its Archæology and Antiquities" (1928). These activities were closely linked with the archæological section of the Belfast Natural History and Philosophical Society, which Mr. Lawlor inaugurated. He also took a prominent part in shaping archæological legislation in Northern Ireland and was a leading member of the Ancient Monuments Advisory Council and sectional editor of the "Preliminary Survey of the Ancient Monuments of Northern Ireland" (1940). His interest and support helped to secure the success of the revived *Ulster Journal of Archæology* (1938), on the editorial board of which he served. He also acted as local secretary for the Society of Antiquaries, and was a member of the Royal Irish Academy.

Born in Ballymena in 1870, Mr. Lawlor came to Belfast and established himself as a linen merchant; and he always took a keen interest in textile history. His character, like his calling, was typical of Ulster. A firm friend to those who knew him well, he was inclined to be stubborn in his archæological opinions and he delighted in controversy. The gap caused by his death will be hard to fill.

E. Estyn Evans.

We regret to announce the following deaths:

Dr. G. T. Bennett, F.R.S., senior fellow and sometime lecturer in mathematics of Emmanuel College, Cambridge, on October 11, aged seventy-five.

Mr. E. H. Clifford, president during 1941-42 of the Institution of Mining and Metallurgy, on October 11, aged sixty-seven.

Mr. A. C. Gardiner, biologist to the Metropolitan Water Board, on August 29.

Prof. W. F. Osgood, emeritus professor of mathematics in Harvard University, on July 22, aged seventy-nine.

Prof. W. M. Tattersall, professor of zoology in University College, Cardiff, on October 5, aged sixty years.

Captain R. D. Williams, officer in charge of clover breeding and other investigations at the Welsh Plant Breeding Station, on October 7, aged fifty-four years.

NEWS and VIEWS

British Drug Houses: Mr. C. A. Hill

Mr. Charles Alexander Hill has retired from his position as chairman and managing director of the British Drug Houses, Ltd. He has been succeeded by Dr. F. H. Carr, who becomes chairman of the company, and Mr. F. C. Oscar Shaw, who becomes managing director. Mr. Hill represents the third generation of a family of wholesale druggists, his grandfather's firm dating back to the reign of George II; he has done perhaps more than anyone else to establish a sound and progressive fine chemical industry in Great Britain and can look back on a business life of outstanding achievement. He was the moving spirit in an amalgamation of drug firms some thirty-five years ago, thus forming an organization large enough to undertake scientific research which led to the development of the manufacture of fine chemicals in a state of high purity for use in medicine. Hill actively encouraged this development on its scientific side, and among other things introduced during the War of 1914–18 the manufacture of pure reagents for use in analysis, microscopic stains, etc., and went on to supply chemicals of high quality for research purposes, displacing Kahlbaums from the position they had hitherto occupied. For this alone British science owes him a debt of gratitude. Later, the progress in medical science led to the introduction of pure hormones, vitamins and chemotherapeutic products. The production of these by British Drug Houses, Ltd., and the spirit of adventure shown by the firm, have won for it as the leading firm in the fine chemical industry a world-wide reputation.

Some fifty years back, when Mr. Hill was training, the Salters Company founded its first fellowships and scholarships, which have been so fruitful in helping some of our best chemists. The Hill family have a long connexion with the Salters Company, of which three generations have been master, and when the turn of Mr. Hill came at an exceptionally early age he was largely instrumental in forming the Salters Institute of Industrial Chemistry. He has filled many public offices, notably as chairman of the Association of British Chemical Manufacturers during two very critical and difficult years, as president of the Drug Club for four years and of the British Pharmaceutical Conference on three occasions. He can look back on a life of remarkable achievement and great development of his industry largely inspired by his efforts.

Organization of Public Medical Services

Readers who are following the discussions in the medical and general press of the proposals for a Public Medical Service put forward in the Beveridge Report will be interested in Sir Arthur McNalty's Report on the Reform of the Public Health Services, issued by Nuffield College (Oxford University Press, 2*s*. 6*d*.), to the sub-committee on post-war reconstruction of local government of which it was submitted. Its author's service as a former chief medical officer to the Ministry of Health enables him to deal with this complex subject with experience and knowledge of the many factors involved. In Part 1 he discusses the need for a wider outlook in medical teaching and practice, for the education of the public and the medical profession in public health and for reforms in general public health which seem to him desirable. Part 2 discusses the activities of the central health authorities, the organization of which is, the author thinks, needlessly complex and expensive. The frequent substitution of one Minister of Health for another, dictated by political considerations, is contrasted with the non-political organization of the Medical Research Council; a non-political director of a governing National Health Department is considered desirable.

Two illuminating pages reveal who actually does the executive work in the Ministry of Health and how many other Government departments are concerned with national health; the establishment of a co-ordinating interdepartmental committee is suggested. In Part 3 a valuable description is given of the activities of existing health authorities. The general medical practitioner, the specialist, the hospital and its ancillary services, the medical officer of health, the dentist and the research worker are all considered, and defects in the existing system are enumerated. Proposals are then outlined for the administration of general and special health services of Great Britain by local authorities or by combinations of these through regional committees. These proposals include full co-operation by the medical profession and provision of medical services for everybody. Lack of space prevents us from giving more than this skeleton outline of the report. Nuffield College is to be thanked for its decision to issue it as a contribution to the discussion of public health re-organization. The College does not, of course, take any responsibility for the views expressed in it, pointing out that it is a research institution which has no collective opinions.

Hospital Physicists' Association

An inaugural meeting of the new Hospital Physicists' Association, held by courtesy at the British Institute of Radiology on September 24, was attended by thirty-seven physicists drawn from hospitals all over Great Britain. The aims of the new Association are to discuss matters arising out of the mutual interests of those engaged in a branch of scientific work which has grown up largely in the last thirty years. Membership is open to physicists attached to hospitals, medical schools, medical or biological research departments. The meeting was followed by visits to the Middlesex, Royal Cancer and Westminster Hospitals on the next day. The afternoon session was devoted to papers. Dr. H. T. Flint spoke on technique with the various radium gram-units; Prof. F. L. Hopwood gave an account of the betatron; Prof. G. Stead discussed teaching for the diplomas and Prof. S. Russ read a paper on the professional equipment of a hospital physicist. Messages of goodwill from the National Radium Commission and the Council of the British Institute of Radiology were read at the meeting. It was agreed that there should be at least three meetings during the year, one of which should be in the provinces. Prof. Russ was elected chairman for the first year, with Dr. Wilson of Westminster Hospital acting as honorary secretary. Prof. Russ reminded his audience that the first full-time appointment as physicist to the Hospital was made thirty years ago. It is likely that to-day between fifty and sixty physicists were engaged in some capacity in hospital or medical research work. A good start was made with the new Association with plenty of evidence of vitality among its members.

Post-War Building Policy

A paper, "Housing, Town Planning and Full Employment" by F. J. Osborn, which has been reprinted from *Town and Country Planning*, points out that while the method of compartmental study of housing policy, town and country planning policy and building industry policy is essential owing to the complexity of the subject as a whole, there must also be co-ordination at a high level before major policy decisions are taken. There are, however, ominous signs of different accentuations and of a clash not far ahead. In particular, Mr. Osborn points out that the Minister of Health's housing circular of March 4 is reactionary in its planning implications, and if the local authorities act upon it before a planning policy is announced it will prejudice that policy and preclude its taking the new direction which the Government has been contemplating.

Analysing the building programme to which the Government has been committed by its White Paper of February last, Mr. Osborn considers that the programme is practical in terms of man-power, of labour, of materials, of finance, and suggests that the main difficulty will be the partly, but not wholly, obsolete dwelling. The White Paper programme cannot be carried out without the replacement of nearly all the pre-1914 dwellings in our old towns and villages. Where vacant sites are available nearby, the procedure could be fairly simple. Either the local authority could build or the Government could encourage private enterprise to do so by offering finance on suitable terms. In areas of high concentration this will not be effective, as many old houses will still have a rental value which will persist longer than twenty or twenty-five years. Consequently the total cost after rebuilding will be the present value and the cost of the new buildings which will replace them, and since these costs added together will make the rent of the rebuilt dwellings too high, the obsolete dwellings will still stand.

Mr. Osborn sees only three methods by which this obstacle could be overcome. One of these he rejects—the State to find the money for buying out the existing values of obsolescent dwellings and cancelling them, so that the sites can be cleared for economic re-building at low density. In his view a combination of the other two will be necessary: the employment of a substantial part of the building industry both by the State and by private enterprise under State stimulus in creating entirely new centres of life and work, and planned extensions of existing small towns; and third, to set statutory limit on the life of an old dwelling, a principle which is included in the Uthwatt proposals. He urges the desperate urgency of a planning policy and the necessity of facing squarely the problems of obsolescence of urban buildings and compensation for land values, and creating the machinery for controlling the location of industry and business, and for building new towns and town-extensions to relieve the pressure on space where the bulk of rebuilding has to be done.

Increase in American Longevity

According to the April issue of the *Statistical Bulletin*, the organ of the Metropolitan Life Insurance Company of New York, the average length of life of the American people has increased by almost one third since the beginning of the century. In 1941 the average expectation of life at birth was 64·36 years, which was a gain of more than fifteen years since 1901. The record was especially favourable for white females, who in 1941 had attained an average length of life of 68·08, as compared with 63·39 years for white males. Coloured persons showed a greater longevity than the white, though the current longevity among the coloured was still ten years less than for the white. The most substantial gain in longevity occurred in childhood, adolescence and young adult life, the death-rates in 1941 below forty being well under one half those at the beginning of the century. Improvements in mortality have also taken place even after forty. The favourable health situation is also illustrated by the fact that about 60 per cent of the babies now being born will live to 65 as compared with only 40 per cent in 1901. On the whole, health conditions have been very favourable in spite of the growing shortage of civilian medical men, the initiation of restrictions on food consumption, the crowding in centres of war industries and inadequate housing.

Conservation of Wild Life in Great Britain

The Universities' Federation for Animal Welfare (temporary address, 284 Regent's Park Road, London, N.3) has issued a circular directing attention to the need for co-ordinating the diverse and often conflicting interests concerned with the regulation of wild life, both fauna and flora, in Great Britain. It is suggested that a central "Wild Life Authority" should be set up by statute and charged with the duty of studying and directing all measures necessary for the control of injurious, and the conservation of desirable, species. Except that the Federation is specially concerned to urge the adoption of humane methods in the destruction of animal pests, its aims seem to differ little from those of several other existing organizations, such as those concerned with national parks, nature reserves, and the like. Further discussion will doubtless emphasize the importance of co-operation rather than competition in this, as in so many other schemes for post-war progress.

Inter-allied Bureau for Educational Reconstruction

AT the sixth meeting of the Conference of Ministers of Education of the Allied Governments held at the offices of the Board of Education on October 5, it was agreed to establish an Inter-Allied Bureau to carry out the practical steps needed to restore educational services in the countries concerned. This Bureau will be the executive body of the Conference. The work to be undertaken by the Bureau includes the purchase and distribution of books and periodicals, the preparation of films and other visual aids and the supply of scientific equipment. These matters are at present being considered by commissions of the Conference. The Bureau was also asked to consider financial needs and methods of contribution by Governments and the establishment of an inter-Allied secretariat.

Recent Earthquakes

THE United States Coast and Geodetic Survey, in co-operation with Science Service and the Jesuit Seismological Association, has determined the epicentres of four recent earthquakes. These are in scattered localities but are all in areas where earthquakes are known to be relatively frequent. The first was on July 23, 1943, at 15h. 52.9m. U.T. and occurred near lat. 10·5° S., long. 117·5° E. This is in the Indian Ocean south of the island of Soembawa, approximately between Java and Australia. The next two came from the same epicentre, the second thus being an aftershock of the first, and together showing the tendency of earthquakes to recur from the same epicentre. The first of these was on July 29, at 3h. 02m. 14s. U.T., from an epicentre near lat. 18·9° N., long. 67° W., which is in the Atlantic Ocean between Nares Deep and the island of Puerto Rico and north of the latter. The aftershock occurred on the next day, July 30, at 1h. 02m. 32s. U.T. from the same epicentre in the West Indies. The fourth earthquake occurred on August 10 at 15h. 13·3m. U.T. from an epicentre near lat. 54° N., long. 161° E., which is approximately in the middle of the east coast of the Kamchatka Peninsula and midway between the towns of Ust-Kamchatsk and Petropavlovsk-Kamchatski. The east coast of the Kamchatka Peninsula forms part of the circum-Pacific chain of instability, lying between the Japanese Islands and the Aleutian Islands. The depths of focus of all four earthquakes are considered normal and the interpretations and calculations are tentative. Data were received from seismological observatories in North and South America, Honolulu, New Zealand and Australia.

Comet Oterma (1943*a*)

AN orbit for Comet Oterma, 1943*a*, has been computed, and its eccentricity is only a little more than half that of Pluto. As a result of this small eccentricity, it will be possible to observe the comet easily throughout its orbit. This is the second comet so far discovered which possesses this distinction, the other comet being Schwassmann-Wachmann (1925, ii). The eccentricities are 0·139 for Comet 1943*a* and 0·142 for Comet 1925, ii; but the periods are very different, namely, 8 years and 16·3 years respectively.

The elements of the orbit of Comet Oterma are given below, but as it is at a considerable distance from the sun and the earth, it is not an easy object except for moderate-sized telescopes.

Nova Aquilæ

A TELEGRAM from Copenhagen announces that this nova attained magnitude 7 at the outburst between April 13 and May 2. Its position, referred to the equinox of 1855, is R.A. 19h. 45·5m., Dec. 8° 06′ N. It is a little brighter than magnitude 12 at present.

Announcements

MR. J. BENSTEAD, general secretary of the National Union of Railwaymen, and Mr. E. Thornton, secretary of the United Textile Factory Workers Association and secretary of the Rochdale Weavers' Association, have been appointed members of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research. Sir John Greenly retired from the Council on completion of his term of office on September 30.

THE College of Physicians of Philadelphia has awarded the Alvarenza Prize to Dr. Ernest Carroll Faust, professor of medical parasitology and acting head of the Department of Tropical Medicine, Tulane University, for his "outstanding contributions to our knowledge of parasitology and tropical medicine".

THE centenary meeting of the Royal Anthropological Institute will be held on October 30. Prof. J. H. Hutton, president of the Institute, will preside, and addresses will be delivered by Sir John Myres on the work of the Institute, and by Lord Hailey on "The Role of Anthropology in Colonial Development" during the morning. The afternoon meeting will take the form of a symposium on "The Future of Anthropology", in which Dr. G. M. Morant will speak on physical anthropology, Prof. V. G. Childe on archæology, Mr. R. U. Sayce on material culture and Prof. R. Firth on social anthropology. The morning meetings will be at the rooms of the Royal Society and the afternoon meetings at the Institute.

THE Nutrition Society has arranged a whole-day conference on "Post-war Nutritional Relief", at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, on November 6. The chair will be taken by Lord Horder and papers will be read by Prof. J. R. Marrack ("Past Experience and Present Position"), Dr. J. Hammond ("Problems of Production in Relation to Post-war Nutritional Relief"), Miss E. M. M. Hume ("Opportunities for Nutritional Research in the Work of Relief") and others. Details of this meeting can be obtained from the hon. secretary, Dr. Leslie J. Harris, Nutritional Laboratory, Milton Road, Cambridge.

Barometer Effect of Penetrating Cosmic-Ray Showers

DURING the past sixteen months we have recorded penetrating cosmic ray showers and barometric pressure. As it was not the main object of the experiment to correlate pressure and penetrating shower intensity, the disposition of the counter arrangement was changed frequently. Altogether two different counter arrangements with fourteen different dispositions of absorbers were used for various lengths of time. One of the arrangements has been described previously[1].

Correlation between barometer and counting-rate was determined in the usual way for each of the separate arrangements. The barometer coefficients obtained for the individual sets of readings were rather uncertain, because of the large statistical fluctuations which were to be expected in consequence of the small counting-rates usual for penetrating showers.

The weighted mean of the fourteen single barometer coefficients appears, however, significant. It was found to be

$$B = -11\cdot7 \pm 2\cdot7 \text{ per cent per cm. mercury.}$$

The stated error is the *standard error* of B.

The value of B was computed from 270 single readings covering 8,220 hours during which 4,363 coincidences were recorded. The root mean square variation of the barometer during this period was found to be ± 0·87 cm. mercury.

The fluctuations around the average values of the individual values corrected for the barometer were found to be statistical. Thus there is no indication of large variations of the intensity due to causes other than changing pressure.

The barometer coefficient B is very large and is of the same order as that found by Cosyns[2] and Auger and Daudin[3] for extensive air showers. This confirms the connexion between air showers and penetrating showers.

The large value of the barometer coefficient is, however, surprising in view of the small absorption of penetrating showers in lead. According to our previous measurements, 30 cm. of lead absorbs only about 20 per cent of the observed shower intensity. This difficulty might be removed by assuming that the absorption of penetrating showers is much greater in air than in lead. Such an assumption appears unlikely, as the penetrating showers seem to consist mainly of mesons, and the absorption of mesons is proportional to mass. The decay of mesons which gives rise to absorption anomalies would give rise to a temperature effect rather than a barometer effect.

An alternative explanation of the large barometer coefficient is that the change of intensity of the penetrating showers with barometric pressure is due not to the absorption of the penetrating showers themselves in air but to the absorption of the primaries which give rise to penetrating showers.

Consider those primaries which at a certain air pressure can just reach the top of a lead absorber placed above the counter arrangement. If 1 cm. more of lead is placed above the apparatus, these primaries will be absorbed in the additional lead. But while absorbed, these primaries will give rise to penetrating showers which will be recorded. On the other hand, if instead of the additional lead absorber the air pressure increases by a corresponding amount, the primaries which would have just reached the top of the absorber will now be absorbed about 100 m. above the arrangement. The penetrating showers which are produced will reach the apparatus too diffused to give rise to coincidences. Thus the barometer effect is a measure of the rate of absorption of the primaries.

This point will be dealt with in detail in another paper.

Boiling Point and Viscosity of Gases

RECENT experimental studies[1] on the compressibility of liquids and liquid-mixtures indicated the existence of a connexion between the compressibility and viscosity. The usual equations representing viscosity – temperature relation of liquids do not, in any form, contain the compressibility function. After trial, it was observed that the viscosity of liquids could be well represented by an equation of the form :

$$\eta = AT^{1/2}e^{B/\beta}, \tag{1}$$

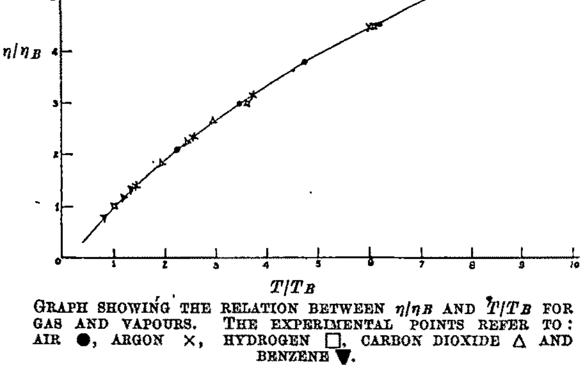
where A and B are constants, and β is the adiabatic compressibility. β, at any temperature, was calculated from the supersonic velocity and the density of the liquid for that temperature.

I was led, further, to consider the question of the viscosity of gases, and from considerations of interaction energy at collision, the following simple formula was obtained, giving the viscosity η at the temperature T :

$$\eta = AT^{1/2} \text{ exp.} - (T_B/T)^{1/2}, \tag{2}$$

$$\text{or } \eta/\eta_\beta = xe^{(1-1/x)}\text{; } x = (T/T_B)^{1/2}, \tag{3}$$

where T_B is the boiling-point temperature and η_B the viscosity of the gas at that temperature. The relationship was tried and found to hold good for air, argon, hydrogen, nitrogen, oxygen, carbon monoxide



GRAPH SHOWING THE RELATION BETWEEN η/η_B AND T/T_B FOR GAS AND VAPOURS. THE EXPERIMENTAL POINTS REFER TO : AIR ●, ARGON ×, HYDROGEN □, CARBON DIOXIDE △ AND BENZENE ▼.

and carbon dioxide, as well as for vapours like benzene, carbon disulphide, chloroform, carbon tetrachloride, etc., throughout the range of temperature where viscosity measurements are available.

The accompanying curve represents η/η_B plotted against T/T_B as given by equation (3). It will be noticed that the observed points for air, argon, hydrogen, carbon dioxide and benzene all fall on this 'universal curve'. The fit is equally good in the case of other gases and vapours. The formula holds for ordinary range of pressures. Since the boiling point depends on pressure, equation (2) indicates the dependence of the viscosity of a gas on pressure. It may be noted, however, that for pressure changes which are not large, variation in the boiling point and the resulting variation of viscosity would be scarcely observable. A change in the indicated direction is, however, to be found in the experimental results of Kundt and Warburg when the pressure change is not very large.

The detailed account of this work is being published elsewhere.

Structure of Geranylamine Hydrochloride

THE ambiguity in the interpretation of fibre diagrams makes it doubtful whether satisfactory solutions for the crystal structures of rubber and the gutta-percha isomers will be possible until a more detailed knowledge of the stereochemistry of the polyisoprene system is available. Accordingly a complete crystal structure analysis has been made on the simple di-isoprene derivative, geranylamine hydrochloride,

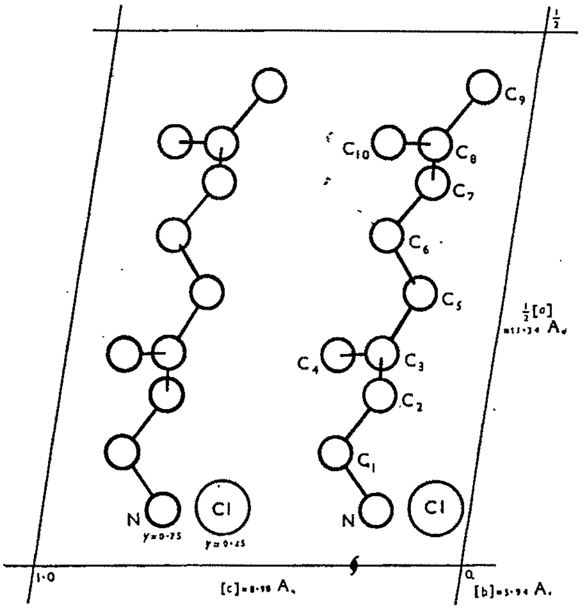
$CH_3.C.(CH_3){:}CH.CH_2.CH_2.C.(CH_3){:}CH.CH_2.NH_2.HCl.$

From the experimental data of 1,060 observed reflexion intensities, it has been possible by extensive trial and error calculations followed by three-dimensional Fourier syntheses to establish the parameters for each atom (excluding hydrogen) to an accuracy of about ± 0·03 A. The space group is $P2_{1/c}$, and a diagram of the two glide-related molecules projected on to half the basal plane of the monoclinic cell is shown in the accompanying illustration. The interatomic distances are as follows :

Cl—N	3·23 A.	C_2—C_3	1·31 A.	C_6—C_7	1·52 A.
N—C_1	1·49	C_3—C_4	1·53	C_7—C_8	1·31
C_1—C_2	1·54	C_3—C_5	1·51	C_8—C_9	1·53
		C_5—C_6	1·43	C_8—C_{10}	1·54

In both isoprene units, which are identical, the disposition of valencies about the ethylenic double bond is strictly planar and the angles are normal to within ± 5°.

The most significant feature of the structure is the shortening of the C_5—C_6 bond, accompanied by a planar configuration of carbon atoms 3, 5, 6 and 7. This implies a hybrid bond comparable, for example, to the formally single bond in butadiene. The double bonds cannot be considered as completely insulated and some degree of triene conjugation must be envisaged, $-C{=}C{-}C \overset{\cdots}{-} C{-}C{=}C-$. Since it is not apparent how the saturated quaternary ammonium pole can be solely responsible for this molecular modification by creating appropriate canonical states, the high electrostatic charge of the N+ must be considered as merely enhancing an effect inherent in the hydrocarbon system. After inductive transmission to the nearer double bond, electron attraction farther along the chain will only be appreciable if it can be relayed by a tautomeric (mesomeric) displacement. Precisely such a mechanism is provided by invoking and developing the incipient conjugation previously suggested[1] as a normal feature of 1 : 5 diene systems by virtue of hyperconjugation involving the α-methylenic C—H bonds.



The details of the complete X-ray analysis will be published elsewhere, together with a discussion of its bearing upon the problems of the natural polyisoprene structures.

A New Technique for the Ultimate Microanalysis of Organic Compounds

UNDER this title, Ronald Belcher and Cyril E. Spooner[1] have described an apparatus for the combustion of organic compounds, consisting of a combustion tube which is not filled with any contact material. The authors refer to their previous publication of a similar macro-method[2], and state that they "originated this unpacked tube technique for the ultimate analysis of Coal", and further say that "so far as we are aware this was the first use of an unpacked tube for this purpose, and we have now adapted it to the micro-scale".

In view of these claims may I be allowed to state that neither combustion analysis without contact material nor its adaptation to the micro-scale are new. In fact, this kind of technique has been repeatedly described by a number of authors from 1864 up to the present time, namely, by C. N. Warren[3],

W. G. Mixter[4], A. Sauer[5], Marek[6], W. Grote and H. Krekeler[7], and A. Schöberl[8]. The latter describes micro-version. As a safeguard against explosion, C. N. Warren fills his combustion tube with asbestos, while Grote, Krekeler and Schöberl enclose the heated area within two sintered plates for the same reason. These precautions do not, however, alter he fact that contact materials are not used. One further variant by H. ter Meulen and J. Heslinga[9] must be mentioned in this connexion. These analysts recommend the use of some quartz splinters in front of an unpacked heated area.

Change of Symmetry of Basic Beryllium Acetate

Preston and Trotter[1] have described a change of symmetry with temperature in the Laue photographs of basic beryllium acetate, $Be_4O(CH_3COO)_6$. This change of symmetry, according to Preston and Trotter, is a reversible one and occurs between 30° and 50° C. At the higher temperature the crystal class possesses three-fold axes with parallel mirror-planes, whereas at the lower temperature only the three-fold axes are present. Preston and Trotter suggest that the increase in symmetry is due to the setting in of molecular vibration of the acetate groups.

We have taken single-crystal photographs of this substance at temperatures between 15° and 80°, using a special Weissenberg camera. These photographs show the change of symmetry very beautifully. Below 25° a spot $(hk0)$ has in general a different intensity of reflexion from $(kh0)$. As the temperature is raised above 25°, however, a change begins which becomes complete at 40° whereby the $(hk0)$ and $(kh0)$ reflexions become equal in intensity. The change is especially rapid between 37° and 40°. As found by Preston and Trotter, the change appears to be completely reversible with no hysteresis.

The Weissenberg photographs give the complete set of $(hk0)$ intensities, and permit the changes in atomic parameters to be followed by Fourier synthesis. The signs of the F values are obtainable from the Pauling and Sherman structure[2]. The results of this work enable the following conclusion to be drawn. As the temperature increases from 25° to 40°, there is a gradual change in the parameters of the carboxyl oxygens from the values $(\overline{0{\cdot}17}\ \overline{0{\cdot}06}\ \overline{0{\cdot}04})$ to the values $(\overline{0{\cdot}17}\ \overline{0{\cdot}05}\ \overline{0{\cdot}05})$ respectively. All other atomic parameters remain unchanged. The low-temperature values $(\overline{0{\cdot}17}\ \overline{0{\cdot}06}\ \overline{0{\cdot}04})$, which correspond closely to the Pauling and Sherman structure, mean that the oxygens are already within 0·23 A. of the 110) planes, which become the mirror planes at 0° C. As the temperature is raised above 25°, there is a gradual displacement of all the carboxyl oxygens until at 40° they lie exactly on the (110) planes.

There is thus no question of the setting in of any abnormal thermal oscillations in this crystal. The effect observed by Preston and Trotter is merely due to a small change in the atomic parameters. The change corresponds to a rotation of the CH_3COO groups about the line joining the two carbon atoms, and is such as to make very little alteration in the distances within the molecule. Some of the intermolecular distances (van der Waals' bonds) are modified slightly.

This crystal would seem to permit a very accurate determination to be made of the size of the –COOH group, and indeed was used for this purpose by Pauling and Sherman. It is not thought that the results derived in the present work by two-dimensional Fourier synthesis are any more accurate than the result obtained by Pauling and Sherman, who used a small number of general intensities. It is thought, however, that the use of three-dimensional Fourier synthesis using all the available general intensities would enable an extremely good determination to be made.

I am indebted to Mr. T. Sheddan for growing the crystals used in this investigation, and for much help in the X-ray photography.

Apparent Vitamin C in Walnuts

THE remarkably high vitamin C content of walnuts has been mentioned by various workers[1,2]. Recent work[3,4] indicates that foods may contain substances which react with the dye and are estimated as ascorbic acid under the usual titration conditions but are not true vitamin C. This apparent vitamin C has now been found in walnuts. Twenty-one samples of five different species have been examined, and all were found to contain considerable amounts of apparent vitamin C (see accompanying table). The *Juglans regia* samples were collected in Kew, Long Ashton and Berkhamsted. All the other samples came from Kew. The flowers of many trees of Juglans and Carya were destroyed by frosts, which prevented the investigation of a wider range of species. The material available was further restricted by the depredations of grey squirrels, at present a serious pest at Kew. The nuts ranged in weight from 2 gm. to 40 gm., and included different stages of ripening up to those in which the shell had become hard and woody. Thus, apparent vitamin C should be found in walnuts which are pickled or used in jam-making, etc. Mapson[5] has found that 14 per cent of the total vitamin C in some walnuts preserved in syrup was apparent vitamin C.

In our investigation the apparent vitamin C was estimated by Mapson's visual method and by our own visual and potentiometric methods[6] on a number of samples. All three methods showed the presence of the apparent vitamin C and (with certain exceptions to be considered in a later communication) the results by the three methods were in reasonable agreement. The apparent vitamin C was not due to tannin, since the results were not appreciably

Species	No. of samples examined	Total vit. C content mgm. per 100 gm.		Apparent vit. C as per cent of total	
		Range	Mean	Range	Mean
Juglans regia	6	1390—2968	2070	19—50	31
Juglans nigra	7	950—2660	1700	23—51	31
Juglans rupestris	6	1022—1606	1360	5—28	18
Juglans cinerea	1	1250	1250	73	73
Carya ovata var. *pubescens*	1	700	700	12	12

affected by removal of tannin by the method of Mirimanoff and Mori[7]. We confirm Gherghelezhiu's finding that the husk (fleshy mesocarp) of walnuts in the later stages of the growth of the fruit contains a higher concentration of vitamin C than the shell (endocarp) and the tissues enclosed within it. We have further found that the fully developed kernel contains very little vitamin C. Our finding that the concentration of vitamin C is greatest in the outermost tissue and least in the innermost tissue in walnuts is in agreement with previous findings on the distribution of vitamin C in other mature fruits, for example, oranges, lemons and tangerines[8], tomatoes[9]. The proportion of apparent vitamin C in the total vitamin C is often much higher in the husk than in the central tissues, and this appears to be associated with a higher pH.

The table shows that our results for the total vitamin C in walnuts were somewhat higher than those found by Pyke, Melville and Sarson in 1942. For example, our mean of 2,070 for *Juglans regia* is above the range of 1,500–1,800 for their results on this species. This may be due to seasonal variations or to other factors to be explored later. When allowance is made for the apparent vitamin C in our *Juglans regia* samples the mean true vitamin C is about 1,470. This is only slightly lower than the range of 1,500–1,800, and in other seasons the mean true vitamin C in *Juglans regia* might easily fall within this range. Thus our findings agree with those of previous workers in showing walnuts to be a remarkably rich source of vitamin C, but also show that walnuts in general contain considerable amounts of apparent vitamin C, which will need to be taken into account to ensure accurate estimations of their vitamin C value.

We are indebted to the Acting Director of the Royal Botanic Gardens, Kew, for providing samples of nuts, and to Miss Elaine Finnigan for assistance in making the extracts.

Details of this investigation will be published elsewhere.

Vitamin C in Walnuts

WE have recently taken the opportunity c estimating the ascorbic acid and 'total' ascorbic aci (that is, ascorbic acid plus dehydroascorbic aci calculated as ascorbic acid) contents of the epicarp of two varieties of ripe edible walnuts (*Juglans regia* In each case the endocarp was very hard, the epidermis was beginning to show dark patches and th epicarp was very juicy and possessed an odour simila to that of juglone (5–OH 1 : 4 naphthaquinone). Th results are given in the accompanying table.

	Conc. of ascorbic acid (mgm./gm. of tissue)	Conc. of 'total' ascorbic acid, or vitamin C (mgm./gm. of tissue)
1. Variety 'Wilson's Wonder'	3·86	4·04
2. Variety ?	8·75	9·30

The method of estimation used was that describe by Lugg[1,2], which makes use of the reduction of th dye 2,6-dichlorphenolindophenol by ascorbic acid and of reactions with formaldehyde as a means o distinguishing ascorbic acid from a number o extraneous reducing substances.

The metaphosphoric acid extracts contained onl small quantities of extraneous reducers, and thes were of the type which does not react readily wit formaldehyde at pH 1·5 and pH 3·5. They contributed only 5–10 per cent of the total reducing capacities of the extracts and their contributions wer scarcely affected by sulphuretted hydrogen treatment in the estimation of dehydroascorbic acid Reduced juglone was found to behave substantiall as a reducer of this type, and consequently onl several per cent of the total reducing capacities o the extracts could be attributed to reduced juglone

In so far as these extracts may have resemble the extracts examined by Pyke, Melville and Sarson[3] who used green, whole walnuts, we confirm thei belief that the great reducing capacities are du almost entirely to the presence of ascorbic acid Attention should be directed to the fact that w found only small amounts of dehydroascorbic aci in our extracts.

A Precipitin Test for Typhoid Fever

TREATMENT of typhoid fever with the serum fron convalescents of this disease is a well-recognize therapeutic procedure. The good results obtaine are believed to be due to passive immunization, as i other forms of serum therapy. From the serologica analysis of a large number of convalescent typhoi sera it was, however, observed that their antibod content, both of *O* and *Vi* antibodies, was universall poor. On the other hand, in spite of their paucit in antibodies, such sera had proved to be ver efficacious therapeutic agents in our hands during th last few years. This experience could not, therefore be reconciled with the statements of Felix and his co-workers on the important role of *Vi* antibody, and its antigenic counterpart, in typhoid immunity and infection; in fact, this antibody forms the principal constituent of Felix's therapeutic anti-typhoid serum. Further experiments were, therefore, undertaken which revealed that when a convalescent serum was injected into human beings, as well as laboratory animals, it led to the production of an appreciable amount of *Vi* antibody and that its therapeutic efficacy was directly proportional to the amount of antibody so produced. These observations could only be explained by assuming that the convalescent serum either stimulated the antibody-forming apparatus in some unknown manner or that it contained an antigen responsible for *Vi* antibody formation. It has now been ascertained that the latter explanation is correct and the typho-precipitin reaction reported here is based on the presence of a *Vi* precipitinogen in the sera of typhoid patients both during infection and during convalescence. The qualitative and quantitative determination of this antigen has been found to be of definite significance in the diagnosis, the prognosis and the treatment of typhoid fever.

Five capillary drops of a *pure Vi* serum (titre 250–500) were measured in each one of a row of precipitin tubes with a capillary pipette (56 drops to 1 c.c.). To these were added equally large five drops of a serially diluted serum under test for its *Vi* precipitinogen content. The mixture, after being well shaken, was incubated at 37° C. for one hour. It was then left in the refrigerator overnight and the reading taken after an interval of 20–24 hours. The development of a deposit and not an opalescence was the criterion of a positive test.

No *Vi* precipitating antigen was found to be present in the sera of typhoid patients during the early stage of disease, especially during stadium incrementi. It could, however, be detected towards the end of stadium fastigium and continued to be present in considerable quantities for 2–3 weeks after the temperature had stayed normal. A large number of normal sera examined did not show its presence nor could it be detected in infections other than typhoid fever. A previous history of *T.A.B.* inoculation did not affect the diagnostic value of the test. Any evidence of flocculation was proof positive that the patient was either suffering or had just suffered from typhoid fever, especially in cases where the isolation of the infecting organism had been unsuccessful and the results of other serological reactions only suggestive of typhoid infection.

From the prognostic point of view the presence of this antigen strongly indicated that the patient was getting the better of infection. In cases complicated with toxæmia, hyper or prolonged pyrexia, abdominal or meningeal involvement and those who relapsed, the *Vi* precipitinogen was either found to be absent or present only in traces at irregular intervals. A fair idea could thus be obtained as to where serological interference with convalescent serum was necessary in cases of typhoid fever.

In the absence of any method by which the potency of a therapeutic convalescent typhoid serum could be assessed, the application of the typho-precipitin reaction gave valuable information as to the suitability or otherwise of the serum of a particular convalescent, the period of convalescence at which the most potent serum was available and its dosage in different types of complications.

Since these experiments proved that active rather than passive immunization resulted from this form of serum therapy, convalescent serum was tried as a prophylactic antityphoid measure. No negative phase was observed, the *Vi* antibody forming within a period of 48 hours. There was no rise of temperature and no localized or generalized after-effects. In view of the general experience that *T.A.B.* vaccine inoculation gives rise to very little *Vi* antibody formation, these results can be considered to be encouraging from the immunological point of view.

Demonstration of the *Rh*-Factor in the Blood of a 48-mm. Embryo

Landsteiner and Wiener[1] described a new antigenic factor, *Rh*, present in 85 per cent of human erythrocytes. This factor they detected by means of agglutination reactions with a suitably absorbed serum obtained by immunizing rabbits and later guinea pigs with *Macacus rhesus* cells.

Human sera containing anti-*Rh* agglutinins and mainly obtained from mothers giving birth to children affected by hæmolytic disease may also be used as typing reagents.

These latter are more suitable since in certain cases they are very potent and obtainable in relatively large quantities. Typing of adult cells with such sera gives clear-cut agglutination reactions.

It was found that the blood of a 48-mm. embryo approximately eleven weeks old could readily be typed (see accompanying table). The agglutination reaction between this blood and potent anti-*A* immune rabbit serum* was very weak, and this relative difference between the strength of the reaction with this serum and human anti-*Rh* sera may indicate that the factor *Rh* develops relatively early in fœtal life.

TITRATIONS OF FŒTAL CELLS WITH HUMAN ANTI-*Rh* SERA AT 37° C.

	Serum				
Cells	1	2	3	4	Anti-*A*
Fœtal	1 : 16	1 : 32	1 : 1	Neg.	1 : 1
Adult	1 : 512	1 : 512	1 : 8	1 : 16	1 : 128

Infection of Laboratory Animals with Johne's Disease and Leprosy

ACCORDING to Francis[1], "until recently it was generally accepted that laboratory animals had not been infected with *Myco. lepræ* or with *Myco. johnei*". As regards the latter organism, in 1913 five out of twenty-three rabbits, six out of forty mice and three out of twelve rats were successfully infected[2], the disease in three of the mice extending from the stomach to the rectum. In some situations even the muscular layer was invaded by the specific micro-organism, although the majority were found in the apices of the villi. The bacteria were grown on F. W. Twort's *Myco. phlei* egg medium or acclimatized to grow on ordinary glycerine-beef broth, although admittedly it would probably have been better to use naturally infected bovine gut. It was easier to infect by injection than by feeding, but by the latter method infection of the mesenteric glands was not at all difficult, although, of course, this does not mean that intestinal disease would have followed had the animals been allowed to survive.

C. C. Twort.

---

[1] Nature, 152, 250 (1943).

[2] *Vet. News*, Jan. 24, 1914.

In the corrected proof of my article, which unfortunately, owing to my absence on leave, did not reach the printers until the article was in press, I had altered the phrase to which Mr. Twort objects to read, "it was generally accepted that laboratory animals could not be infected with *Myco. lepræ* or with *Myco. johnei*". This correction was made in the reprints. In my original paper[1], I gave a summary of Twort's work but also referred to subsequent experiments which had led workers "generally to accept that laboratory animals could not be infected with *Myco. johnei*". Owing to the almost complete failure of the subsequent experiments, it has not been possible to study Johne's disease in laboratory animals. It is hoped that by the use of very young animals this will now be possible.

John Francis.

Propagation of Potatoes

It is interesting in view of the recent correspondence[1,2] on this subject to recall that a century ago the planting of whole tubers was by no means the only method employed for propagating the potato. Louden ("Encyclopaedia of Agriculture", 1844) lists the use of small cuttings, sprouts, shoots, eyes, and buds, as methods of propagation, and in "Encyclopaedia of Gardening" these and other methods are described. The following notes are based on descriptions given in the 1871 edition of "The Encyclopaedia of Gardening", although, so far as can be judged from the preface, they are likely to be identical with descriptions given in the earlier (1834) edition.

Cuttings were made of young stalks or branches, 5–6 in. in length, in May or June and struck in showery weather in the open or under a hand-glass or in pots. Layers were made in June or July when the potato stalks were 1–2 ft. long, and after layering, these shoots, according to Louden, emit roots at every leaf and produce full-grown potatoes the same year. Suckers may be removed in June, with a few roots attached, and planted carefully when, like layers, they will produce a late crop of tubers.

In seasons of scarcity the sprouts generally found on store potatoes in spring may, when carefully planted in loose well-prepared soil, be made to yield a crop. Propagation by portions of tuber is, according to Louden, the only method fit for general use. He writes: "In making the sets or sections reject the extremes or watery end of the tuber as apt to run too much to haulm, and having the eyes small and in a cluster. Reject also the root or dry end as more likely to be tardy in growth and as according to some producing the curl. Then divide the middle of the potato so as to have not more than one good eye in each set. Where the potato scoop (described and figured in 'Encyclopaedia of Agriculture') is used, take care to apply it so that the bud or eye may be in the centre of each set which this instrument produces of a semi-globular form. The larger the portion of tuber left to each eye, so much the greater will be the progress of the young plant. The scoop is only to be used in seasons of scarcity when the portion of tuber saved by it may be used for soups for the poor or for feeding cattle."

Future of Technical Colleges

The attention of the Council of the Association of Technical Institutions has been directed to the letter on the above subject by Dr. H. Lowery.

The Council is much concerned at some of the statements which are made in that letter. These statements give a very inaccurate picture of the work done by the technical colleges at the present time, and it is doubtful whether in the majority of cases they would ever have been true. In those technical colleges where degree courses are undertaken they are certainly not in any way of a makeshift character, and it would be untrue to say that they have grown out of a makeshift system. In many of the larger technical colleges the staff and laboratory equipment compare most favourably with those of the universities, and not only are the numbers of students comparable, but also the results obtained are academically excellent. The numbers of students taking honours degree courses of the University of London in the technical colleges of the country are quite comparable with those in the internal colleges of the University itself, and it must be remembered that the term 'external' has now quite changed in significance, since the technical colleges working for London degrees are inspected by representatives of the universities and only offer degree courses after full approval by the University has been given.

There is much in Dr. Lowery's letter with which we should very heartily concur, but there would appear to be no useful purpose served by deprecating the outstandingly excellent work on the degree side which many technical colleges have undertaken for some time now, and it is particularly unfortunate that in submitting the evidence to support his case, he should have used statements so far from the truth.

GEOGRAPHICAL DISTRIBUTION OF *Arenaria humifusa* Wahlenb., NEW TO THE FLORA OF SPITSBERGEN

By DR. NICHOLAS POLUNIN

Fielding Herbarium, University of Oxford

OF outstanding interest, and the subject of much controversy, is the tiny boreal caryophyll now generally known as *Arenaria humifusa*. It was described as a species by Wahlenberg[1] so long ago as 1812, but afterwards became more widely known as a supposed sub-species or variety or even mere *forma* of *Arenaria ciliata* or *A. norvegica*—or, latterly in America, as the full species *A. cylindrocarpa* Fernald. In 1935 Prof. Rolf Nordhagen[2], after having gathered together (as he used to say) "a very great material" of it, resurrected the designation *Arenaria humifusa*; this is probably the correct one, material from the two sides of the Atlantic being apparently identical and moreover showing a similar range of variation, for example, in habit and pubescence[3].

But the bulk of Nordhagen's much cited book[2] "Om *Arenaria humifusa* Wg. og dens betydning for utforskningen av Skandinavias eldste floraelement" is concerned, as the title implies, rather with discussions of the distribution and historical-phytogeographical significance of the plant, which had already attained some fame in this connexion through the attention of Prof. M. L. Fernald[4], and has since been thus cited very widely, for example, by Abbe[5], Hultén[6], and others, including Fernald, who recently styled it[7] "the famous relict of northern Europe". The rather attractive and soon popular contention was that with some other plants of 'senescent' or 'conservative' (as opposed to 'aggressive') tendency, colonies of *Arenaria humifusa* had persisted in isolated areas which had been ice-free 'nunataks' throughout at least the latest Pleistocene maximum and had survived there, or at least near, until the present day. Meanwhile, examination of one of these 'refugia' by Abbe[5] having brought forth rather conflicting evidence, Raup[8] and Wynne-Edwards[9] tended among others to be at least reserved in their judgment, the last-named putting forward an alternative hypothesis.

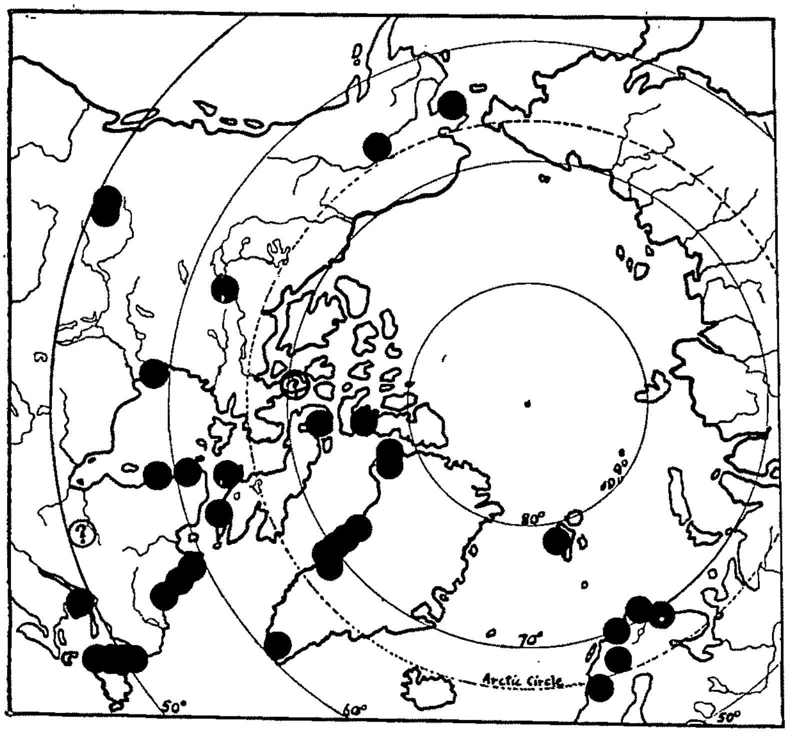
I am not myself prepared at present to enter the controversy, though I would like to see it stimulated to an early conclusion. On one hand I have observed enough plants growing successfully near to, or even on nunataks within, present-day glaciers even in the far north to believe that such 'persistence' is a distinct possibility, while on the other hand I cannot help recalling that substrate and the lack of competition may be of great importance respectively in determining plant populations locally and in aiding ecesis, that migratory birds as well as plants have their own habitat preferences, that a single disseminule carried by any one of all the birds migrating in a millennium (so to speak) "would be sufficient to stock a country or island with any given plant"[10], and finally that "sea ice . . . forms a splendid field for the transport of wind-borne seeds and fragments of plants"[11] particularly of coastal habitats.

Meanwhile, the case of *Arenaria humifusa* may yet present no serious problem, but may help in general clarification: for its actual geographical range is very different from what Nordhagen[2] and others took it to be from the facts to which they had access. Thus I have myself found it in so many regions where it was supposed to be absent that it now seems unnecessary to consider its range as disrupted in the north except by aquatic and other wholly unsuitable substrates. Rather was it the extremely diminutive stature and insignificant nature of the plant, coupled with its somewhat exacting habitat requirements[12] (it appears to be calciphilous and unable to withstand competition, hence most frequent near shores and on mountains), that led to its being extensively overlooked. Given suitable conditions it is able to spread well enough; indeed, the greatest number of individuals of it that I have ever seen at all close together grew (in 1934 and 1936) on the open calcareous gravel of the recently constructed railway and settlement of Churchill, Manitoba, on the west coast of Hudson Bay, where the country is flat for very many miles around.

Now to the 'total distribution' as given by Nordhagen[2], and as generally known in 1935, we can already add the following *regions* (as opposed to minor stations which are of course more numerous): Alaska—west coast and mountainous centre[13], subarctic North-West Canada[14], subarctic Hudson Bay—both east and west coasts[15], Canadian Eastern Arctic—four additional regions[12], South-West Greenland[16], and finally Spitsbergen.

This impressive series of additions from widely separated areas in the last few years suggests that, apart from Iceland and East Greenland and the northern parts of the Canadian Western Arctic, which are quite inadequately explored, and where the species may well occur, it can be considered as generally distributed across arctic and subarctic (climatically delimited) Europe and America right to the extreme west of Alaska. Its distribution to the south may admittedly be somewhat disrupted, but it seems at least as likely that this is bound up with the progressively fewer 'open soil' and otherwise suitable habitats in that direction as that it is dependent upon glacial history, though to be sure we still have to answer the provoking question of how the plants got there. Meanwhile, much support for some 'persistence' seems to be derivable from the study of endemics[4].

The Spitsbergen record of *Arenaria humifusa* is deserving of comment as it has not previously been published; it is the newest and perhaps the most surprising of all. Very recently Mr. A. J. Wilmott and I were revising in the British Museum some material which I had collected in Kongsfjord (Kings Bay, *c.* 79° N. on the west coast of the main island) more than a decade ago and found, in a pile of sheets provisionally labelled "? *A. Rossii*", and which incidentally included several specimens of *Arenaria uliginosa* Schleich. apud Lam. which had only once previously been confirmed from Spitsbergen[17], one which obviously belonged to *A. humifusa* (it was nothing like the locally common *A. ciliata* var. *pseudofrigida*), being practically inseparable in all visible characters from material from Finmark so determined by Prof. Nordhagen and also from material from Newfoundland collected and determined by Prof. Fernald as *A. cylindrocarpa*. Arrived back at Oxford I found among my own unmounted and still not worked up material a duplicate of the same number (152 from the vicinity of Ny-London, a largely limestone district on the north shore of Kongsfjord); apart from the variable characters mentioned above and others which were not always visible, this specimen checked wholly with my Canadian



DISTRIBUTION OF *Arenaria humifusa* WAHLENB.

Eastern Arctic and subarctic material approved by Prof. Fernald and also with my south-west Greenland specimens[16]. Indeed, *A. humifusa* is a highly characteristic little plant that cannot well be mistaken for any other, at least in the Arctic. Its total distribution at present known is indicated on the accompanying map ; but it seems safe to conclude that some entirely fresh regions and many new stations will be added in the future, further to warn phytogeographers against *assuming* absence of a species until proper search (which still can scarcely be absolute) has been made. New regions may even include the British Isles, where, especially in the Hebrides and Scottish Highlands, many interesting northern plants have southern 'outposts'.

There remain among doubtful reports three which appear to be supported by specimens : (1) "Lake Mistassini (J. M. Macoun)" upheld by Robinson[18] and Nordhagen[2], and which the former, always a cautious student, probably saw, for he cited "*A. ciliata*. . . . Var. (?) *humifusa*. . . . *A. humifusa* Whlb. . . ." from "Mt. Albert, Gaspe, *Allen, Porter* ; Lake Mistassini, *J. M. Macoun*, and what is with scarcely a doubt the same thing at Kicking Horse Lake in the Rocky Mts., *J. Macoun*. (Greenland, N. Europe)". I have strong suspicions that the basis of the report by the younger Macoun[19] of *Stellaria humifusa* Rottb. from Lake Mistassini, where he and A. P. Low collected in 1885, belongs in reality to *Arenaria humifusa*, as the two plants might easily be confused and, moreover, this lake is an inland, freshwater one around the margins of which it would amaze me to find the habitually halophilous *Stellaria humifusa*. Meanwhile, be it noted that confirmation of this station would go a long way towards filling the apparent 'gap' between Hudson Bay and the Newfoundland and Gaspe 'outposts' to the south-east. Next we have (2), the specimen in the British Museum from Sir John Ross's second voyage, cited by Simmons[20] and afterwards by Nordhagen[2] as most likely from Boothia Felix. Although the expedition spent much time in that region, where the plant may indeed be expected to occur, they also visited points in the Holsteinborg district of West Greenland[21] where *Arenaria humifusa*, even if it has not yet been found, probably grows (it is "rather common" not far to the north[22] and also occurs to the south[16]), while on the voyage home they camped on beaches in the limestone region of northern Baffin not very far from Arctic Bay, in the vicinity of which I have found the plant several times on similar calcareous terrain near the sea. As we have no known means of telling whence this specimen from Ross's second voyage came (for unfortunately it lacks any indication as to locality, collector, or even date) it seems wisest to mention it only with a strong query. Finally (3), the report by Schischkin and Knorring probably refers to the well-known station on Fiskerhalvøen[2], even if these authors give it as Karelo-Lapland rather than the 'arctic belt' (see maps and lists at beginning of Komarov's Fl. U.R.S.S. series). Meanwhile, it seems remarkable for a plant elsewhere so widespread that there should be only the one known station in all Russia, the whole of Siberia being apparently excluded from its range, although the plant is known to extend virtually from westernmost Alaska eastwards around the remaining more-than-half of the polar cap.

SENSITIVITY OF THE EAR

THE difficulty in securing accurate values of the minimum stimulus that the ear can detect is reat. In the first place there are differences in the earing mechanisms of various individuals tested. xcept for those with some definite hearing defect, iese differences largely depend on age ; as one rows older the response of the ear becomes less, hiefly at the higher frequencies. Measurements of inimum hearing stimulus thus vary with the age f those being tested. Another difficulty is in measurig the minimum stimulus. According to an article y W. A. Munson (*Bell Lab. Rec.*, 21, No. 10 ; June 943) two references have been widely used. One is ie rms. pressure of the sound wave at a point in a ee sound field where the listener's ear will later be laced. This is the simpler of the two, and is parcularly applicable to studies of the usual mode of earing, that is, without the use of telephone receivers similar devices. The other is the pressure at the ar-drum. This reference avoids uncertainty as to ow the pressure, measured in the air previously to e listening test, would be modified at the ear-drum y the head and ear of the listener, and is particularly seful in studying the mechanism of hearing. It volves great technical difficulties, however, since e space in front of the ear-drum is small and almost accessible.

Regardless of which of these two methods is used, e pressure involved is very minute—less than 1,000 dyne/sq. cm. A pressure of this order of agnitude distributed over the ear-drum results in a rce of the order of only $1/10^8$ oz. As an organ for tecting pressure changes, the ear is thus far more nsitive than our tactile organs, since a touch of this ghtness would be imperceptible. Even at the upper nit of hearing, the force is only some thousandths an ounce. Vibrating pressures greater than this come tactable rather than audible and result in e sensation of pain. Any air wave with an rms. essure above the threshold value enters our conciousness as sound, and the sound becomes louder e higher the pressure. Since it is the loudness ther than the pressure that we are directly conscious , some scale for measuring loudness is also desirable.

The results of a large amount of work were summarized some years ago by Fletcher and Munson and was decided to use the loudness of a 1,000-cycle ne as a reference. This frequency is widely used a test tone throughout the Bell System, and it has e advantage of being very close to the frequency nge for which the ear is most sensitive. Since in neral the relationship between the magnitude of a nsory response and its stimulus is logarithmic, it emed desirable to use a logarithmic scale, and for nvenience the loudness-level of a 1,000-cycle tone as arbitrarily taken to be the intensity level. oudness-level at any other frequency or combination frequencies is taken to be equal to the intensity-vel of a 1,000-cycle tone that sounds equally loud. lthough loudness-level is measured on a logarithmic ale, and thus corresponds in magnitude to a decibel ale, the unit is called a phon instead of a decibel indicate that the thing measured is basically fferent from power.

At 1,000 cycles the threshold of hearing in a free ld is just about at 0 intensity-level, which also stifies making the loudness-level and intensity-level ual by definition at this frequency. At 1,000 cycles, erefore, an increase in intensity-level results in an equal increase in loudness-level. This equality is found not to exist at other frequencies, however.

To the question : How little do we hear ? the only safe answer is : it all depends. What we hear is a sequence of periodic pressure changes in the air, but how small the pressure changes may be, given a normal young ear, depends on the rapidity of the changes. The ear is most sensitive when the pressure cycles are occurring at rates between 1,000 and 5,000 times per second, since we can then detect changes of less than a thousandth of a dyne/sq. cm. At both higher and lower frequencies, the sensitivity falls off. The studies that have determined these minimum perceptible pressure changes, and the many others that have established units of measurement and adequate techniques and apparatus, have provided the foundations for the extensive studies of hearing that have been carried on in the Laboratories.

CERAMICS FOR HIGH-FREQUENCY INSULATION

ACCORDING to an article by M. D. Rigterink (*Bell Lab. Rec.*, 21, No. 9 ; May 1943) electrical porcelains which are satisfactory and useful materials for low-frequency currents have been replaced for high-frequency currents by new ceramic materials which have far smaller power factors. This replacement becomes absolutely essential at elevated temperatures such as are encountered in power vacuum tubes in which the insulator operates almost red hot. The power factor of most ceramics increases very markedly with increase in temperature, this causing more conversion of electrical energy into heat and producing a cumulative effect which may lead to a breakdown in any but the very best materials.

The most widely used of the improved ceramics are the steatites, this term now being applied to all synthetic ceramic materials which are prepared with talc as the principal raw material and which have magnesium metasilicate as the principal crystalline phase. Steatite bodies are prepared from mixtures of 60 per cent or more talc, 30 per cent or less kaolin, and the remainder usually of alkali or alkaline earth oxides or compounds that will decompose to give these fluxing oxides. The formed ware is heated from 1,200 to 1,400° C. on a controlled heating and cooling cycle. During this heat treatment the fluxing oxides combine with part of the magnesia, alumina, and silica given by the talc and the clays to form glasses which in turn dissolve more of these constituents as the temperature rises. In addition to glass formation, chemical reactions take place between the solids and between the solids and liquid glasses ; crystallizations also occur as the temperature is lowered, and finally crystalline transformations are produced. These complex changes cause the mixture to shrink and to become the hard, dense material known as a steatite ceramic.

Dielectric properties of the steatite ceramics vary considerably, depending on the amount, kind and proportions of fluxing oxides that are used in their preparation. The alkalis are particularly detrimental, and the alkaline earth oxides appear to be especially beneficial. Other variations are caused by the grinding and mixing of the raw materials, the firing cycles, and the nature and the amount of impurities present. All the steatites have unusually high transverse, tensile, and compressive strengths, these values frequently being as much as three times as high as the corresponding values for electrical porcelains. They also possess resistance to cold flow, ability to withstand high temperatures, resistance to all common chemical agents except hydrofluoric acid, and low porosities.

Steatites have replaced porcelains for some uses solely because of their greater mechanical strength but more frequently on account of their improved dielectric properties. The useful range of dielectric constant for steatite ceramics varies only from five to eight. Loss of electrical energy in these insulators depends more on the power factor than on the dielectric constant.

Another interesting and important property of these steatite ceramics is that those which have good insulating properties for direct current may not be as satisfactory for alternating current. For example, ceramic bodies with the same direct current resistances were prepared for which the values of tan δ at 100 kc. varied by a factor of more than twenty-five. Thus, where a.c. and d.c. voltages are superimposed the dielectric properties for both have to be considered in comparing different materials.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, October 16

Institute of Physics (X-Ray Analysis Group) (joint meeting with the **Manchester and District Branch**) (in the Physics Department, The University, Oxford Road, Manchester), at 2.30 p.m.—Sir Lawrence Bragg, F.R.S.: "The Physical Optics of X-Ray Analysis"; Short Papers and Exhibition of Apparatus, etc., relating to Industrial Problems.

Association of Scientific Workers (North-West Area) (in the College of Technology, Sackville Street, Manchester).—Sir Robert Watson Watt, F.R.S.: "The Freedoms of Science".*

Sunday, October 17

Association of Scientific Workers (North-West Area) (in the University, Liverpool).—Sir Robert Watson Watt, F.R.S.: "The Freedoms of Science".*

Monday, October 18

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5 p.m.—Dr. E. C. Willatts: "Physical Names for the Map of Great Britain".

Tuesday, October 19

Society of Chemical Industry (Agriculture Group) (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 2.30 p.m.—Mr. W. Morley Davies: "Lime in Agriculture".

Institution of Professional Civil Servants (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—The Rt. Hon. Sir Stafford Cripps, P.C.: "Radio and International Relations".

Royal Photographic Society (Scientific and Technical Group) (at 16 Princes Gate, South Kensington, London, S.W.7), at 6 p.m.—Dr. G. W. W. Stevens and Mr. P. C. Smethurst: "High-Resolution Microphotography—Graticules".

Friday, October 22

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Prof. F. C. Lea: Presidential Address.

Friday, October 22—Saturday, October 23

Town and Country Planning Association (at the Royal Empire Society, Northumberland Avenue, London, W.C.2).—Conference on "Country Towns in a National Planning Policy".*

Friday, October 22—Sunday, October 24

Institute of Industrial Administration (at the Waldorf Hotel, Aldwych, London, W.C.2).—Conference on "Management in Action".

Saturday, October 23

Sheffield Metallurgical Association at 2.30 p.m.—Discussion on "The Education and Training of Metallurgists" (to be opened by Dr. Edwin Gregory).

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned:

Teacher of Mathematics and General Science for Technical D School and College—The Chief Education Officer, Education Offic Park Road, West Hartlepool (October 20).

Educational Psychologist (full-time)—The County Medi Officer, Public Health Department, Shire Hall, Nottingham (Octo 20).

Assistant Agricultural Chemist—The Principal, Agricultu Institute and Experimental Station, Kirton, Boston, Lincs. (Octo 21).

Teacher of Physics—The Principal, Acton Technical College, H Street, Acton, London, W.3 (October 22).

Lecturer (full-time) **in Physical and Inorganic Chemistry**, a **Lecturer** (full-time) **in Zoology, with Botany or Physiolog** The Clerk to the Governors, South-East Essex Technical College School of Art, Longbridge Road, Dagenham, Essex (October 22).

Lecturer in Mining—The Clerk to the Governors, Techn College, Infirmary Road, Chesterfield (October 23).

Lecturer in General Science for the Junior Technical Colleg The Principal, Derby Technical College, Normanton Road, De (October 23).

Lecturer in Mathematics, and an **Assistant Master** to tea **Science** and subsidiary **Mathematics**—The Principal, Kingston Te nical College, Kingston, Surrey (October 25).

Teacher of Engineering Subjects, and a **Teacher of G graphy**—The Principal, West Ham Municipal College, Romford Ro Stratford, London, E.15 (October 25).

Assistant to the Advisory Mycologist—The Advisory Mycolog School of Agriculture, Cambridge (October 30).

Engineering Graduate (or equivalent qualifications) to te chiefly Mechanical Subjects—The Principal, County Technical Coll Dartford, Kent.

Assistant Engineer for the British Guiana Public Works Dep ment—The Ministry of Labour and National Service, Central (Te nical and Scientific) Register, Alexandra House, Kingsway, Lond W.C.2 (quoting Reference No. E.767).

EDUCATIONAL RECONSTRUCTION (3)

THE NEEDS OF YOUTH

SINCE 1937 the promotion of facilities to enable young persons and adults to use their leisure in a wide variety of activities covered by the general terms 'social and physical training' has been recognized as an appropriate element in the education service. Between that year and the Education Act of 1918, local education authorities had been concerned only with the leisure activities of young people attending some school or other educational institution and under the age of eighteen. An amendment made in 1937 swept away these limitations, and particular attention has since been concentrated on the interests and requirements of young persons who have left school and passed outside the confines of formal training. But the objective of the National Fitness Council, as its name suggests, was only with physical fitness. In throwing out of focus a perception of the general needs of youth, this was a hampering limitation, and this is now recognized in the recent White Paper on Educational Reconstruction.

With the outbreak of war it was felt necessary to maintain and extend the influences which had contributed to the well-being of the young life of the nation. Accordingly, in November 1939, Circular 1486 was issued by the Board of Education empowering local education authorities, in conjunction with the national voluntary organizations, to set up youth committees which could immediately begin to formulate an ordered policy for youth and also suggest lines on which developments might proceed after the termination of hostilities.

Despite the restrictions and difficulties that the War has brought, the service of youth has made considerable progress. To-day, there is a far higher proportion of the young people of Great Britain associated with healthy and recreative leisure-time activities than at any period of our history, although the proportion is still lamentably low.

In order to bring together the ideas and experiences that have been obtained in the youth service since its inauguration, the president of the Board of Education set up a Youth Advisory Council in August 1942 to consider the position of the youth service as a part of the educational system after the War. So that its terms of reference might be clarified, the Youth Advisory Council was asked to assume : (1) that the school-leaving age would be raised to fifteen without exception, (2) that the period from fifteen to eighteen would be treated in some degree as an educational period in the sense that adolescents would be regarded as remaining the concern of the education service, and (3) that a system of compulsory part-time education during working hours would be established for all young persons after they had ceased full-time schooling, up to the age of eighteen.

The members of the Council were drawn from local education authorities, the national youth organizations, pre-service training corps as well as individuals distinguished for their work with young people. In presenting its report*, which, of course, is in no way a statement of considered Government policy, the Council has made a valuable contribution towards promoting a more general understanding of this highly important field of youth service. The report is one to which no summary of its principal conclusions could do justice. To grasp the mixture of hard-headed realism and imaginative understanding which has inspired its originators, the report should be read in its entirety.

The Council has wisely refused to be tied to the precise age-groups which limit the entry of young people to certain organizations but has expressed the wish that, after the War, no age lower than twenty will be accepted as the appropriate upper limit to the youth service. Only by thinking of a boy or girl as a whole person, with a past and future as well as an adolescent present, can the subject be seen in proper perspective. It is with this 'wholeness' of life in mind that the Council begins its report with some comments on homes and families, the national system of formal education, religion in youth activities and the quantity and quality of work which young people are called upon to do.

Warm tribute is paid to the enthusiasm and endurance with which young people have met the challenge of war, and the belief is expressed that they will respond as courageously to the challenge of the post-war world if they are given a careful and thorough training for citizenship. To make this possible, certain conditions will have to be fulfilled. Thousands of young people have to live in surroundings which make it almost impossible for them to become good citizens. This scandal must be removed at the earliest possible moment. No fitter comment on this situation could be found than one written by Dr. A. E. Morgan in "The Young Citizen". "There is no reason why the environment of a working lad in his leisure hours should be inferior to that of a university undergraduate."†

It is part of the policy of H.M. Government to raise the school-leaving age to fifteen without exemption; but the Council recommends that full-time attendance at school up to sixteen years of age should be aimed at as soon as conditions permit. Up to the age of eighteen the first call on the working day should be education; the transition from full-time schooling to full-time employment should be a longer and more regulated process. Continued education must be regarded not as a concession granted by the employer but as a right given by the community. During the later years of compulsory school attendance, a wider variety of activities should be encouraged. The provision made for education for industry, and particularly for technical education, is inadequate and should be considerably expanded. Any raising of the school-leaving age would imply compulsory maintenance grants or allowances.

In the choice of employment service, existing arrangements are irregular and spasmodic. Young persons ought to be able to enjoy the benefit of expert advice given in the light of the individual' aptitudes and in conformity with the best moder methods of vocational guidance and selection. Loca education authorities, employers, organized labou and the Ministry of Labour should unite to enabl all young people and their parents to obtain skille industrial guidance, both on first entry into employment and afterwards. Choice of employment power should be made a statutory obligation of the loca education authority, and until the law is altered t this effect, advisory committees under the administration of the Ministry of Labour should includ members of the local education authority as well a members of the local youth committees.

Hours of work are too long. During war-time n boy or girl under sixteen should work more than maximum of forty-four hours weekly; for thos between sixteen and eighteen the maximum shoul be forty-eight hours. As a permanent peace-tim regulation the permitted maximum for all up t eighteen should be forty-four hours inclusive of part time school. Overtime and the accompanying hig wages present grave social dangers which are likely t persist until a greater sense of responsibility can b fostered in the young people themselves. The qualit of work, too, is often as objectionable as the quantity If there is no solution of this problem inside workin hours, increase in the amount of a young worker' leisure is necessary and urgent. The imperative nee inside industry is to restore to every kind of work tha sense of social significance which has largely bee lost as machines have replaced men. Any tendenc in the youth service towards the 'academic' in education should be resolutely opposed.

It is impossible to segregate religion from oth activities; it must form the background of home school, work and leisure alike. The Council is co cerned to see preserved, or born, a genuinely Christia civilization, one whose members are not all necessaril professing Christians but one in which the Christia belief in God and all that is consequent upon it f human liberty and brotherhood, the Christ-like ide of life, and the preservation of the fundamental idea of truth, goodness and beauty, set the tone f society. Religion is a positive need for young people the Council insists that it is nothing more than the due that religious opportunities should be provide Such opportunities must, of course, be of varyin character in order to satisfy not only the mult plicity of needs of the children but also the man demands of the parents. For religion is of such a pr foundly personal character that any semblance regimentation or any attempt at bringing abo homogeneity are bound to prove failures.

With this background clearly outlined, the repo goes on to discuss the fundamental problem of t right use of young people's leisure. Here it is of fir importance to start from the point of view of th young people themselves and not from the angle what the various agencies concerned can contribu to what they consider to be the right use of leisu In emphasizing the wholeness of life, the Coun here brings out what is probably its most importa recommendation, namely, that unless we wish to re a people incapable of exercising its freedom, there must be preserved a part of life in which young people should be left free to choose their leisure activities. These should not in any way become the subject of compulsion, and the greatest variety of opportunities for the right use of leisure should be provided. This recommendation is fully borne out by some research carried out for the Workers Educational Association during 1934–37 into the activities of youth organizations. The chief characteristics of young people inside these organizations were reported to be: (1) a dislike of externally imposed discipline, (2) a dislike of organization and complex loyalties, and (3) a severe code of discipline imposed from within the organization on members themselves and backed by open criticism and imposition of standards. Everyone is familiar with the boy or girl who is not by temperament attracted to communal activities and who finds the life of a club or any other organized body of their contemporaries overwhelming and uncongenial. In war, as in peace, it is undesirable to apply compulsion to the leisure hours of young people.

---

* The Youth Service after the War. (H.M. Stationery Office, 1943.) 6d. net.

† Young Citizen. (A Penguin Special.) P. 178.

Further, the leisure hours of young people are so few that at first sight the whole paraphernalia of the youth service seems irrelevant and undesirable. So ong ago as the year *c.* 38, Ecclesiasticus wrote that "the wisdom of a learned man cometh by opportunity of leisure", and it is time that this truth was fully apprehended.

Even more harmful than the excessive hours of work is the usual practice of limiting to one week the annual holiday of the working boy or girl. Despite the many difficulties that would arise, the community as a whole would benefit if all young workers could enjoy an annual holiday long enough to give them a real opportunity for recreation. A minimum annual holiday of twenty-four working days (inclusive of the ix statutory holidays) is suggested, twelve of the days o be consecutive. Facilities and opportunities for the proper enjoyment of these holidays should be made available. To meet the needs of young people n their daily leisure, the work of voluntary rganizations and statutory authorities should be trengthened and extended.

The youth service should operate to lead young people towards adult life; the fitful demand of adolesence is its desire to achieve maturity. The separate 'youth centre' with the buildings of the day continuation school (or young peoples college) as its physical nucleus cannot be regarded as ideal for this purpose, and it is suggested that statutory authorities in providing communal premises for youth work should lan them as part of adult community centres. This s essential to the process of guiding youth through the "delicate weaning stage from childhood to adulthood; from subjective dependence to objective independence; and if it is to be introduced to the main business of life, which is the attainment of the fullest elf-expression, fraternally, economically, politically and spiritually."*

So that we may be prepared, provision should now e made for Great Britain as a whole, as part of educational reconstruction after the War, of facilities in town and country for educational, social and physical recreation.

When the youth service scheme was announced in November 1939, it was realized that the relation between the statutory authorities and the voluntary organizations might prove the stumbling-block to progress. Good will has pushed the stumbling-block aside and it has been proved that both have a part to play and that their respective contributions are essentially complementary. In the near future the problem of the statutory authorities in youth service work will become more pressing and their responsibilities greater. As these responsibilities increase, they will do well to remember that it was through the ideals and enthusiasm of the voluntary organizations that the first work for adolescents was undertaken, and that the policies and programmes of the voluntary organizations have been built on well-tried experience.

To make their much-needed contributions, the voluntary organizations must be strengthened financially; any scheme devised for this purpose should be flexible and so administered as to encourage free development. Extension of the help which the voluntary organizations now receive from public funds should be accompanied by some measure of public control over their activities. This could be done without interfering with the development of the organizations, if they issued periodical reports, published headquarters accounts, and submitted their finances to the scrutiny of the Board of Education. Where a local education authority gives local grant-aid to a voluntary organization, the authority, as well as the Board, should have the right of informed inspection.

This measure of control is not likely to meet with serious opposition from the majority of the voluntary organizations. One or two may object to any measure of public control and look aghast at what they consider to be the sinister approach of bureaucracy. For their part they must realize that many individuals who serve the voluntary organizations and have considerable power in their deliberations and pronouncements are as much paid servants as the officials of the statutory authorities. It may be that of late too much emphasis has been placed on the word 'voluntary' and that the time has come when at least some of these national organizations recaptured the spirit of service which animated their founders and which has meant so much to the welfare of the community.

The growth of the pre-service cadet corps has been so rapid that to-day they comprise a large proportion of the total number of boys who belong to a youth organization. Their development has been greatly helped by the considerable financial assistance given to units by the Service Departments. This assistance is related to the needs of war, and it is far from certain that, when the pressing needs of war are past, the Service Departments will be prepared to subsidize cadet work to anything like the extent to which they do to-day. Moreover, the motives which lead boys to join the corps in time of war will have lost much of their force. If the corps are to continue in peace to play any considerable part in the youth service, they must greatly develop the educational, social, and recreative side of their work. This suggests that the general responsibility for their administration, direction and finance should be turned over to the Board of Education and the local education authorities. At the same time it is essential that the Service Departments should prescribe and retain the supervision of both the content and the standards of the pre-service training.

---

* "Adult Education", *Quart. J. Brit. Inst. Adult Educ.*, 26 (Septemr, 1941).

The position of the National Association of Training Corps for Girls differs materially from that of the boys' pre-service training organizations. While it provides a certain amount of general pre-service training, it is not attached to any one branch of the Armed Forces and has never been under the control of the Service Departments. It is presumably an organization which, by the provision of a general type of training, offers to girls the opportunity of voluntarily continuing their education irrespective of a specific objective. It is desirable that the National Association of Training Corps for Girls should continue in existence after the War as a uniformed organization. The Board of Education and the local education authorities should extend to it the same degree of support as is given to other voluntary organizations.

The youth committees which were set up after the issue of Circular 1486 differ from one another both in constitution and efficiency. The essential qualification for membership is youthfulness, if not in years at least in spirit. It is far from certain that this 'young-mindedness' has been sufficiently insisted upon. Taking the broad view, however, the experiment of laying joint obligations on the local education authorities and the voluntary organizations has been successful, and the co-partnership needs increasing to the fullest possible extent. After three years of experiment, a useful function would be served if the Board of Education collected and issued for the guidance of all youth committees the information which by now must be available about the ways in which this very practical form of education in citizenship has developed.

The Council's broad survey of the field of youth is important for the emphasis it lays on the 'wholeness of life'. The home, school, employment, leisure, service and religion all interact for the development of intellect, skill, personality and character, and the Youth Advisory Council has wisely insisted that the whole upbringing of a boy or girl shall be in the widest sense educational. This is all to the good, for frequently do we end our arguments concerning the various failings of present-day youth—from lack of social sense to that of musical appreciation—with the everlasting demand, education and more education. By their challenging and long-sighted recommendations in the interests of youth, the Youth Advisory Council, fairly representing the opinion of the majority of youth workers in Great Britain, has presented the President of the Board of Education with advice to which he will no doubt pay the closest attention. Much depends upon it.

INDUSTRY AND SOCIETY (I)

RELATION TO THE NATION

A SIGNIFICANT indication of the widesprea
interest in the organization of industry afte
the War and the relations between industry an
government can be seen in the references to thes
questions at recent important company meetings suc
as those of Boots Pure Drug Company, the Associate
Portland Cement Manufacturers and Associated Ele
trical Industries. At the last-named meeting, Si
Felix Pole emphasized the efficiency and adaptabilit
of industry as it is now organized; he leaned toward
a planned organization of the cartel type, much a
Lord McGowan did in a recent article in the *Sunda*
Times on the place of combines and cartels. Thes
and other addresses in the past few months sho
that the place and functions of private enterprise i
the national economy are under re-examination.

Many factors have contributed to this positio
War-time developments and the experience of wa
time controls, the growth of restrictive practices, fo
all their denunciation by industrial leaders of hig
repute, our closer contacts both with Soviet Russi
and with the United States—the recent visit to Grea
Britain of Mr. Eric A. Johnson, president of th
Chamber of Commerce of the United States, ha
demonstrated some important differences in th
British and the American view of creative privat
enterprise—have all played their part, and the gener
point of view has been well put by Mr. Herber
Morrison, particularly in his speech at Leeds in Apri
A case can be made for private enterprise in appr
priate fields, as well as a powerful case for publi
enterprise. There is no case whatever for privat
un-enterprise, or for private control without the sp
of free competition or of real social purpose.

That much will be generally admitted, particularl
by scientific workers concerned with the prosecutio
of an adequate programme of scientific and industri
research as an integral part of post-war plans. Tl
fresh scrutiny of private enterprise to-day, in spite
recognized shortcomings of State control during tl
War in certain directions, is due to the widesprea
appreciation that large sections of British indust
were anything but enterprising in the twenty yea
between the two Wars. Attempts in some reports o
reconstruction, such as those of the Federation
British Industries, the Association of British Char
bers of Commerce, and, to a lesser extent, the stat
ment on "A National Policy for Industry", to glo
over this record, and a timidity of outlook simu
taneously apparent have not allayed this concer
On the contrary, they have stimulated fresh fea
that such important associations are looking
policies of restriction and monopoly destined in t
long run to be as fatal to their own interests as to t
policy of full employment which public opinion,
Great Britain as elsewhere, is coming insistently
demand.

That much clearly emerges from the surv
"Industry After the War. Who is Going to Run It
which Charles Madge has produced as the first of t

"Target for To-morrow" Series*. But neither Mr. Madge in his summary, nor Sir William Beveridge in his introduction, goes any deeper into the fundamental issues than the statements already criticized. The Unilever paper, "The Problem of Unemployment", the more recent Nuffield College paper, "Employment Policy and the Organization of Industry after the War", and the report of the Sub-Committee of the Liberal Party on the relation of he State to industry, it is true, go nearer to the roots of the matter. Even in these, however, no real attempt is made to sort out the fundamental issues and to ask the all-important questions regarding he relations of Government and industry before an attempt is made to define the targets or formulate he lines of policy.

Such fundamental thinking is an essential preliminary, and without it plausible schemes for the self-government of industry are more likely to be snares or delusions than contributions to the solution of the problem of full employment. The fact is, as Dr. A. D. Lindsay points out in his recent volume, "The Modern Democratic State", that industrial or economic organization is not just an instrument; it partly moulds the society which uses it. Some ecognition of this truth lies behind the general belief that the measures open to unregulated and unaided private enterprise will not suffice to vary the incidence of the trade cycle and to maintain a constant and high level of employment, but that a national economic policy is required to deal with cyclical unemployment. Before, therefore, we can determine the right relations of government and industry in a democratic society, we must have clear conceptions ot only of the nature of that society but also of the lace and functions which government and industry are to serve in it. It is the confusion on this point that has darkened counsel in so many of the proposals and discussions on industrial self-government, planning and the public control of private enterprise nd production. The distinction between government nd management is often overlooked and Dr. Lindsay's volume is to be welcomed for its contribution to the clarification of the issues on this point alone— contribution which at least merits comparison with that of Prof. Ernest Barker's "Reflections on Government".

The leadership which industry has failed to supply is an essential in a society in which industry is to be real social function, and the attention which has been directed to this point of late, notably in the statement on "Industry and Education" issued by Nuffield College, indicates that an attempt is being made to meet the need. If democracy is to survive, it will have to employ and use, as Dr. Lindsay truly remarks, every scrap of skill and knowledge and leadership it can secure. "A modern democratic State is only possible if it can combine appreciation of skill, knowledge and expertness with a reverence for the common humanity of everyday people."

That is the conception of equality which democratic institutions must express along with liberty. The function of the State being to serve the community and in that service to make it more of a community, a democratic government must be sensitively aware of the conditions which are making equality and liberty hard to maintain. There are clearly certain minimum rights and minimum standards of economic security which it must provide. But it must also be swift to diagnose and to deal with such obvious and outstanding evils as widespread unemployment, which so poison the life of a people that they make real community impossible.

In a democratic society this cannot be the task of the government only. The government must seek to enlist the help of all those free associations in which the life of society finds expression, and notably is this true of industry. The first step to self-government of industry is not so much freedom from government control as association and integration with the workers themselves. The joint production committees already set up in Great Britain may well be a step in this direction, and with a wise educational policy may so broaden the basis of recruitment that natural leaders are thrown up as they should be, and the closer integration of industry with the life of the community rendered possible.

Whether the joint production committees will provide exactly the type of machinery required to achieve this purpose requires further examination. They should be regarded as an experiment the results of which require study and comparison with those obtained in other experiments, for example, the autonomous groups of M. Dubreuil. Dr. Drucker has suggested a guild structure in industry, and unquestionably it should be one of our prime purposes to develop genuine local self-government in this sphere, to develop as Dr. Drucker urges, in "The Future of Industrial Man", social institutions in industry through which industry can become a functioning self-governing social community.

That would do much, by giving the individual industrial worker social status and function, to arrest the social atrophy which mechanization has often introduced. It would make also a decisive contribution to the establishment of the public confidence on which the Nuffield College statement rightly lays stress. Again, it is linked up with what Dr. Drucker considers the other essential in the establishment of a functioning society, namely, making the decisive social power into legitimate power, or in other words power derived from the consent of the governed. Clearly there is no surer way of gaining public confidence in the conduct of industry than the demonstration beyond question that it is directed to serve the needs of society and not merely the private interests of those who are engaged in it, whether they be investors, management or the workers as such. Misgivings on such points are in fact the main ground of uneasiness at present; they lead to the fear that price-fixing and restrictions on production are determined by considerations of private profit and not of public service and social needs.

The Nuffield College statement on "Industry and Education" does well to stress this factor of confidence, for only by such means can we ensure the full co-operation of workers, management and consumers that is essential both for efficient production in the technical sense and for the service of social needs. In this sense morale is no less important in the normal operation of industry than it is in the war effort. The success of post-war reconstruction policy, and in particular that directed to full employment, depends at least as much upon the standard of morale in industry and in the nation as a whole as does our ability to win the War.

---

* Industry After the War: Who is Going to Run It? By Charles Madge, in consultation with Donald Tyerman. (Target for Tomorrow, No. 1.) Pp. 64. (London: The Pilot Press, Ltd., 1943.) 3s. 6d. net.

Given, therefore, that one of our objectives should be to create conditions in which industry has the best chance of developing as a social service, and in doing so develop real self-government and co-operation between management and workers, we can consider the machinery by which that broad objective can best be achieved. If one of the essential functions of the State is to remove the disharmonies which threaten the common life of the community, the more positive and constructive functions which the government is rightly expected to perform make it difficult to draw a clear line between the functions of a modern government and those performed by voluntary associations. The essential problem is in fact to arrive at such a balance between voluntary association and the compulsory organization of the State as will ensure the maximum harmony in communal life while keeping the State as the servant and not the master of the community.

The clue to the right solution here is not hard to find. It is a great mistake to assume that the strength of a government is increased by adding to its powers, because additional powers always impose additional duties. There are tasks which only a central government can perform; and if it is to discharge those tasks well, it is important to devolve on local authorities or even on voluntary associations all the functions they can competently perform. In the decision to centralize authority the *onus probandi* should always rest with those urging centralization.

Much of the present dissatisfaction with the machinery of government in Great Britain can be traced to violation of this principle. Failure to delegate responsibility or authority effectively may well be responsible for the central government becoming immersed—doubtless with all the exigencies of the War in extenuation, if scarcely in excuse—in a mass of detail that has prevented it from considering those broad issues of policy and making the decisions, for example, in regard to land policy, planning and building which are required before local and regional authorities can proceed with the more detailed planning and execution which is their responsibility. The consequences in industry are similar. As both the Nuffield College statement and the Unilever paper show, there are fields in which the Government must announce its decisions and lay down the broad lines of policy before industry can make its own plans, and this is independent of the exact structure of industry, and whether it takes the form of private enterprise or State enterprise. Unemployment, investment policy and exports are all matters of this type where Government initiative, guidance and control are the first requisite.

Unfortunately, Mr. Madge, in his "Industry Afte the War", fails to discriminate between the contro and management of industry. The difference i important. If a measure of public control is adopted for a particular industry, the management of industry in the sense of the technical conduct of its day-to-day affairs must still be efficient. The fears as to Government control are largely due to this confusion between control and management, and its removal must b one of the first steps to secure the effective integration of industry as a social activity, whether from th point of view of securing the co-operation of worker or the confidence of the public in general.

INFANT MORTALITY

Birth, Poverty and Health

A Study of Infant Mortality. By Richard M. Titmuss. Pp. 118. (London: Hamish Hamilton, Medical Books Ltd., 1943.) 7*s.* 6*d.* net.

AMONG indexes of disease and death none offer a more inviting field for research in the fiel of vital statistics than the infant mortality-rate. It distribution among different social classes an different communities has an extremely high disper sion, and the general level within a single composit social group has unique features. While chances o death at other ages declined steadily during the whol of the last three quarters of the nineteenth century both in Britain and in Western Europe as a whol the death-rate under one year of age fluctuated abou the same figure—150 per thousand for England an Wales—until about 1899. From 1900 there has bee a continuous and spectacular change. During th subsequent half-century the number of infant death per thousand in our own country has fallen by mo than sixty per cent. This being so, it is surprisin that contributory social agencies have attracted s little inquiry to date. One reason is a hangov from an ideology widely current in the period whe evolutionary concepts furnished a convenient rationa for an economy of unrestricted private competiti and colonial misgovernment. What Sir Henry Mai called the "beneficent private war which mak one man strive to climb on the shoulders of anoth and remain there" was the prevailing creed of th universities when the existence of differential mo tality first forced itself on public discussion. Foremo among articles of the creed was the postulate th class mortality and morbidity differences have the origin in differences of genetic constitution.

In conformity with a type of non-sequitur endem in writings about what one calls eugenics on th side of the German Ocean and *Rassenhygiene* on th other side of the North Sea, differences which a inborn are also irremediable. By the same toke the probable existence of genes which affect resistan to smallpox would invalidate vaccination, and th certain existence of genes which affect susceptibili to cancer would veto radium therapy; but the were too few who recognized this dilemma. Nineteen century thought about heredity could not as y see beyond a miasma of misconceptions arising fro identification of character differences with gen which determine them within a particular enviro mental framework. This we may amply deduce fro the writings of Galton, than whom few writers ha more powerfully influenced, and more deplorab sidetracked, lucid thinking about the statistics of human populations. As a representative specimen of the Galtonian *Weltanschauung* the following is sufficiently eloquent: "We may, therefore, broadly conclude that the only circumstance, within the range of those by which persons of similar conditions of life are affected, that is capable of producing a marked effect on the character of adults is illness or some accident that causes physical infirmity. The impression that all this leaves on the mind is one of some wonder whether nurture can do anything at all, beyond giving instruction and professional training. There is no escape from the conclusion that nature prevails enormously over nurture when the differences of nurture do not exceed what is commonly to be found among persons of the same rank of society and in the same country."

It would be difficult to extract from deliberate utterances of reputedly competent men of science a combination of *naïveté* and nonsense so transparently belied by results of modern research on human nutrition, or, as R. M. Titmuss shows, more demonstrably belied by relevant data about the trend of mortality during recent years. In 1911 and 1931 the infant death-rates of Class I, the most prosperous section of the community in the Census categories for England and Wales, stood respectively at 76 and 33. Those of Class V—the least prosperous of the Census categories—stood at 153 and 77. From these facts alone several conclusions are compelling. Within so short a period as this no changes of the genetic structure of a population can have contributed significantly to either of two outstanding features of the shift. At both ends of the social scale the chances of death during the first year of life had gone down by about 50 per cent in less than one generation; and the chances of survival of a navvy's baby at the end of the period were as good as the chances of survival of a barrister's baby at the beginning of it.

For the benefit of those who have forgotten what eugenists were saying in 1911, there is no lack of evidence from the record of human superstitions. They are accessible in back numbers of the *Eugenics Review*. The difference between 76 (Class 1) and 153 (Class V) was due to nature, and the efforts of Newsholme and others who sought to alter the *status quo* by changes of nurture were necessarily foredoomed to failure. Oddly enough, this presupposition went hand-in-hand with a hallucination which identified the fittest with survivors from the benefits of the most expensive medical amenities available for safeguarding offspring of prosperous parents against death from 'natural' causes. We now have before us the factual verdict of history. Contrary to what eugenists claimed at that time, events have shown that it is possible to reduce the death-rate of Census Class V to what that of Census Class I was in 1911. So the onus of proving that it is impossible to lower the deaths of Class V to the 1941 level of Class I lies on those who intrepidly and intransigeantly reiterate arguments conclusively disproved by what has happened before. In short, as Titmuss says: ". . . there are no medical, social or economic reasons why advanced communities should not achieve a rate of 15, for the knowledge formerly lacking is now abundantly available."

Besides making accessible in a readable narrative facts too apt to remain buried in census volumes on the shelves of libraries, R. M. Titmuss has undertaken a careful scrutiny of differential infant mortality to meet objections against the admitted imperfections of census classifications. The results of his analysis do not weaken the conclusions tabulated by the Registrar General's Office. They reinforce them. Therewith, the author of "Birth, Poverty and Health" has also extracted from official records another class of facts familiar to too few people and specially relevant to the role of nature and nurture. Among all classes of deaths which occur in the first year of life none is less susceptible to *known* differences of environment than those which occur in the first month. If genetic differences between social classes play an important part in differential mortality among infants, we should therefore expect to find a high dispersion of figures for neonatal deaths. For 1931 (England and Wales) we find that the ratio of neonatal deaths to deaths between 1 month and 1 year in Class I was three times as high as in Class V.

This supplies very strong evidence for the conclusion that the contributory role of environmental differences to observed differences of infant mortality is much greater in the least prosperous than in the most prosperous social groups. The same conclusion emerges from a classification of deaths with respect to diseases at present curable or incurable. The former account for about 86 per cent of total infant mortality. We are, therefore, in a position to state within fairly narrow limits the margin of further reduction which social legislation directed towards the fullest utilization of biological knowledge could achieve. The result fully justifies the anticipation cited above, and forestalls any ground for complacency. As Dr. Newfield remarks in the editorial foreword: "The absolute infantile death-rates among the poorer groups have indeed declined; but relatively to those in the economically better-favoured groups, they are higher, far higher, than ever before."

"Birth, Poverty and Health" is a refreshing indication that there is a rising generation of statisticians and social biologists who have thought their way through the luxuriant overgrowth of misconceptions which Galton's generation planted and Pearson's followers watered. It is temperate and stimulating, lucid and well-documented. It lifts a class of problems calling for immediate legislative action above the fog of political indignation to the level of a factual analysis of human needs and human knowledge available for implementing their satisfaction. As such it deserves a wide circulation among those who cherish what Bacon called the true and rightful goal of science. It is also valuable, because it emphasizes a need long overdue for more exhaustive research into the precise nature of the social agencies contributory to the decline of infant mortality, and the persistence of the differentials the author discusses.

LANCELOT HOGBEN.

EARLY AMERICAN AERONAUTICAL HISTORY

The First Century of Flight in America

An Introductory Survey. By Jeremiah Milbank, Jr. Pp. x+248+24 plates. (Princeton, N.J.: Princeton University Press; London: Oxford University Press, 1943.) 18s. 6d. net.

JOSEPH CONRAD, in his Nostroms, wrote "The Air of the New World seems favourable to the art of declamation". Judging by Mr. Milbank's book, the air of the New World, and particularly the air of New Jersey, has been very favourable to the art of reclamation of early American aeronautical history.

On December 17 next will occur the fortieth anniversary of that astonishing first controlled flight in a power-driven heavier-than-air craft which was to rank with the discovery of gunpowder, the coming of the printing press, and the wireless as a major event in the history of the world.

Mr. Milbank's history begins with Benjamin Franklin, who was fortunate enough to witness in France the ascent of the Charles balloon on August 27, 1783. In a letter to Jan Ingenhousz, physician to the Empress Maria Theresa, Franklin wrote, prophetically, "It appears, as you observe, to be a discovery of great importance and which may possibly give a new turn to human Affairs. Convincing Sovereigns of the Folly of wars may, perhaps be one Effect of it, since it will be impracticable for the more potent of them to guard his Dominions. It is a pity that any National Jealousy should, as you imagine it may, have prevented the English from prosecuting the Experiment, since they are such ingenious Mechanicians, that in their hands it might have made a more rapid progress towards perfection, and all the Utility it is capable of affording." He stirred up his own countrymen about the new invention with little delay in a letter to the American Philosophical Society.

On January 7, 1785, Pierre Blanchard and Dr. Jefferies crossed the English Channel from Dover in a balloon, and landed in France on almost the exact spot where 273 years earlier Henry VIII and Francis I met on the Field of the Cloth of Gold.

Blanchard was French, Jefferies was American (he was born in Boston and graduated at Harvard College in 1763), and the hazardous crossing which began at 1 o'clock in the afternoon finished at a quarter to four. There followed the usual spate of entertainment which seems to follow any dramatic flight (except, of course, the most important one of all, by the Wright Brothers !). Whether it was due to the two months entertainment or to some other cause, Jefferies gave up his aerial experiments and resumed his career as a medical man in Boston.

The first American ascent was in a captive balloon by a boy of thirteen, as the balloon was not large enough to lift a full-grown man.

Under the patronage of George Washington, Blanchard was the first to make a free ascent in America, on January 9, 1843, his sixteenth ascent. Although the ascent received considerable publicity, the Americans showed great apathy in taking up ballooning. The Frenchmen Guille (1879) and Eugene Robertson (1825) raised a certain amount of interest with their flights. Between 1830 and 1834 Durand with his ascents gave a fillip to the new art, but he was unable, in 1840, to persuade the general in command of the American forces fighting the Indians in Florida to use balloons for "spotting Indian camp fires by night excursions".

The one man in America who did most to direct attention to ballooning was John Wise (1808–79). He designed many of his own balloons, made many hundreds of ascents, carried the first air mail in America, and made every effort to get his countrymen interested in a projected voyage across the Atlantic by balloon. He was the inventor of the ripping panel which removed considerable danger from balloons landing in winds. His book, "Through the Air", gives much data on air currents, atmospheric conditions at various heights and electrical phenomena. Wise had a profound faith in the future of aeronautics and believed that the crossing of the Atlantic by air was not far distant.

Fired by Wise's exploits, another American, T. S. C. Lowe, rose to ballooning fame. To him belongs the credit of demonstrating the use of the military balloon for observation purposes in the Civil War. General Greely wrote: "it may be safely claimed that the Union Army was saved from destruction at the battle of Fair Oaks, May 31 and June 1, 1862, by the frequent and accurate reports of Professor Lowe." (All balloon experts in America were called professors.)

Following the Civil War, a new generation of balloon exhibitionists, acrobats and parachute jumpers took full advantage of the increasing interest of the American public. They served one useful purpose: to make that public air-minded and to arouse the interest of scientific men.

By 1890 more and more attention was being concentrated on the heavier-than-air machine, and the possibilities of the airship. Edison, ten years before, had begun his first investigations into heavier-than-air flight.

In 1883 came the first claim for a glider flight, by J. J. Montgomery, and in 1889 Octave Chanute began his great contributions and was publishing his classic work "Progress in Flying Machines". In 1895 was established the first American Aeronautical Society. Two years earlier, Langley, secretary of the Smithsonian Institution, Chanute, A. F. Zahm and others convened an aeronautical conference at Chicago at which Dr. Zahm read a paper on stability of aeroplanes and flying machines, Hargrave one on flying machine motors and cellular kites, and Langley his famous paper on the internal work of the wind. Here Mr. Milbank's history ends. Ten years after that meeting the heavier-than-air machine was an accomplished fact.

Mr. Milbank has written not only an extremely well-documented book but also one which may indeed be the basis for others. The author gives a complete list of his sources of information, and it is a tribute to his careful research into contemporary records. But as he rightly says in his preface, "This outline history of Aeronautics in the United States before 1900 has only scratched the surface".

It is to be hoped that the author will now begin to dig deeply. J. L. PRITCHARD.

LOWER AQUATIC FUNGI

Aquatic Phycomycetes: exclusive of the Saprolegniaceæ and Pythium

By Frederick K. Sparrow, Jr. (University of Michigan Studies, Scientific Series, Vol. 15.) Pp. xix+785. (Ann Arbor, Mich.: University of Michigan Press; London: Oxford University Press, 1943.) 5 dollars.

THE lower fungi which inhabit fresh and salt water have been for a long time a neglected and mysterious assemblage of organisms, worked fitfully by some investigators, more intensively by others, but standing badly in need of a thorough investigation. Few of them are known to be of economic significance, many are supposed to be rare, most of them are tiny and demand very painstaking observation; to mycologists in general these fungi have been things to be avoided. The lack of any comprehensive account in English, and of a modern survey in any other language, has deterred would-be investigators, who have recoiled from the unwelcome task of searching large numbers of scientific periodicals in a variety of languages, perhaps in the end to find imperfect descriptions difficult to understand.

Much of this is now changed. Dr. F. K. Sparrow, a graduate of Harvard now teaching in the University of Michigan, has provided an admirable guide to the aquatic Phycomycetes, and has abolished, or at any rate greatly diminished, many of the difficulties associated with them. He shows how these fungi can be obtained, often easily; he indicates how they may be observed, and he sets out clear figures and descriptions by means of which they can be recognized.

The generous financial support available to scientific workers in the United States enabled Dr. Sparrow to travel widely. He made two long visits to Great Britain, travelled in Europe, collected freely and observed intensively on both sides of the Atlantic, met mycologists having interests in common with himself, and altogether gathered an abundant harvest of experience, observations, material and impressions. In all ways he equipped himself to write his book, for he added deep and wide reading to his direct work on the fungi. Behind all this there was the tradition set up by the eminent mycologists who have adorned Harvard for the last half-century or so, a tradition of careful observation first, and speculation very much second.

As the title indicates, certain aquatic Phycomycetes are not dealt with in the book; that is because those fungi have been described in detail, and in fairly recent times, by other authors. Dr. Sparrow decided to fix the scope of his book by biological rather than by taxonomic limits. This has entailed a few omissions, and has meant that the descriptions of some of the groups are incomplete taxonomically. Two main series of fungi are described, drawn from what other mycologists have called the Archimycetes and the Oomycetes. The result justifies the scheme, and, now that Dr. Sparrow has shown how useful a biological criterion can be in obtaining a feeling of unity in a book, it is to be hoped that he, or another as well qualified as he is, will earn our gratitude by producing an equally satisfying account of the remaining aquatic fungi.

The book consists of a general introduction followed by a systematic account of the fungi, alliance by alliance. Each alliance is treated uniformly, with a general account of the development, morphology and biology of its members, followed by full taxonomic details of the families, genera and species. The liberal supply of keys makes the book easy to use. About half the space is devoted to the Chytridiales, fungi to which Dr. Sparrow has given much study, and of which he has greatly extended our knowledge. The Chytridiales, together with two smaller alliances, the Blastocladiales and the Monoblepharidales, are grouped together because of their uniflagellate zoospores, in parallel with a biflagellate series made up of the Plasmodiophorales, Saprolegniales, Leptomitales, Lagenidiales and Peronosporales. This convenient and acceptable grouping, though based on a character of the zoospore, is supported by other characters, and seems to bring out well the natural relationships of the fungi concerned. The systematic part is followed by a long list of the substrata inhabited by aquatic Phycomycetes, a very extensive list of references, and a full index. The illustrations are good and clear; it is interesting to note among them a portrait of Zopf, a mycologist whose work seems never to have had the recognition it merits.

The general introduction and the sectional introductions are clear and concise. In them, Dr. Sparrow includes firm, quiet statements of his own opinions, given without dogmatism. That sort of sober treatment characterizes the book and makes of it, in the best sense of the word, a solid contribution to the progress of botany. "Aquatic Phycomycetes" takes its place as the standard book on its subject; it is likely to be a long time before another author arises, able and qualified to write a better.

While the book will appeal chiefly to mycologists, it will be of the utmost value to all students of aquatic life, and will stimulate renewed investigation of the aquatic fungi. It should be in every botanical laboratory, and would not be out of place in zoological surroundings, for numbers of aquatic Phycomycetes have associations with animals, and we do not yet know how significant these are. It may be, for example, that Catenaria can be used to secure the biological control of the liver fluke.

A word of congratulation is due to the University of Michigan, for it is that body which has made possible the publication of the book. In these times, especially, it is refreshing to find that there is still money and sentiment in the world, available to support the production of books on specialized subjects remote from ordinary experience and of no obvious economic application.

B. Barnes.

HISTORY OF X-RAY ANALYSIS

The History of X-Ray Analysis

By Sir Lawrence Bragg. (Science in Britain Series; Published for the British Council.) Pp. iv+24+4 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1943.) 1*s*. net.

The British Council has done well to add this pamphlet to its "Science in Britain" series. Nobody else now alive could have written it with quite the same zest as Sir Lawrence Bragg: he has produced an essay in close accord with his title, the "History of X-Ray Analysis"; and that is what is wanted.

There are certain things worth saying even if, in other contexts, they have been said or implied before. One is the footnote on p. 3, which explains once and for all, to the layman, the difference between X-ray analysis and radiography. It is surprising how deep-rooted is the confusion about this in the popular mind. Another is the description of early days spent battling with a crystal structure, even "living with it", and dreaming of it for a year. To recapture such a mental atmosphere is exhilarating, and the gentle rebuke to the younger generation may not go wholly unheeded. Anyway, we shall do well to recollect it when looking up crystal structures, as we do now, with little more concern than finding telephone numbers. For the rest, there is much of interest, though maybe along somewhat more traditional lines.

The concluding paragraph raises a hope, now probably forlorn. It is that this little book might reach Prof. von Laue, to lift a trifle his distress of mind, and to assure him that a certain haunt of students and their teachers in Munich, as it was in 1912, is still an honoured memory.

F. Ian G. Rawlins.

POTATO EYES AS READILY TRANSPORTABLE 'SEED' FOR THE COLONIES

By SIR GEOFFREY EVANS, C.I.E.
Royal Botanic Gardens, Kew

IT has been known for some time that the propagation of potatoes from small pieces of sets and even from single eyes or sprouts is quite feasible. Such methods have indeed been employed by nurserymen and others when the rapid increase of some specially good or new variety was necessary. It is only recently, however, that the practicability of introducing some such system into commercial methods of cultivation has really received careful attention.

It is obvious, of course, that if satisfactory crops can be raised by using only a small portion of the tuber as 'seed' there will be a great saving, as the remaining portion will be available for food or processing purposes, since this would represent a saving of between 80 and 90 per cent of the total crop. This is a matter of particular importance in war-time, when every pound of food is wanted and all waste must be eliminated. It is especially so in the U.S.S.R. where so large an area of food-producing land is in enemy hands.

Recent information[1] seems to indicate that practical means have been devised by Prof. Lysenko and his co-workers of the Lenin All-Union Agricultural Academy and that most of the potato tuber is now used for food, small portions of the skin, including the eyes, being reserved for seed purposes. Similar unorthodox emergency methods have been discussed by Copisarow[2]. Likewise, Polunin[3] has shown the possibility of small-scale cultivation of potatoes from detached sprouts.

But apart from the actual saving of food involved by these methods is the great saving of transport. In Great Britain alone, several hundred thousand tons of seed potatoes are moved from Scotland or Northern Ireland each spring to meet the demands of potato growers in England, and if 70 or 80 per cent of the bulk and weight involved could be eliminated it would mean a considerable relief to railways and the transport system, and would probably do away with the awkward delays in delivery that are bound to occur under existing conditions.

The particular problem that was placed before me, however, was the supply of potato seed to certain British overseas dependencies. Among those countries where the potato has now been established as a farm crop may be cited Cyprus, Malta, Palestine in particular, and also Kenya and parts of Nigeria. In these countries the potato has come to stay and is consumed not only by Europeans but also to an increasing extent by the natives themselves. In most of these places, however, experience seems to indicate that fresh seed needs to be imported either each year (especially in places where it is found impracticable to keep seed from one planting season to the next) or at regular intervals in order to re-introduce fresh and vigorous stocks.

War-time transport conditions have rendered these seasonal importations most difficult to maintain. Either transport is not available at the right time, since all shipboard space is required for military stores, or the voyage is so delayed by the hazards of war that the 'seed' arrives in a spoilt condition and often too late for the planting season.

It was decided, therefore, to explore the possibility of sending planting material by air, and it soon became evident that the sending' of seed potatoes of the usual trade size by this means would not only be too costly but would also be impracticable owing to the weight and bulk of the seed. There seemed to be two ways of meeting this difficulty. One was to dispatch the 'seed' in the form of very smal chats the size of marbles, and the other was to send the 'eyes'. The latter seemed to offer the greatest possibilities for air transport as the weight involved would be least.

The problem consists of devising some simple means by which the smallest possible portions or 'chips' of the tuber could be dispatched with safety by air with a reasonable assurance that when planted they would be capable of producing a crop at least comparable with that grown from normal seed. Allowing for reasonable delays in packing, dispatch and distribution, it was considered that such 'chips' would have to retain viability for about a month or so and would have to withstand a certain amount of rough handling.

A study of recent Russian literature seems to indicate that methods of this sort have been adopted on a very large scale in that country, but unfortunately no details are available of the actual method used or the means employed to 'cure' the cut end of the seed and to preserve viability until the planting season arrives. It seems obvious that unless the cut end can be sealed rapidly the entry of fungi or bacteria mus speedily result in the death of the eyes. Experiments to this end have been conducted in the United State by the Franklyn Research Co. and other workers[4].

Arrangements were made to lay down some observation plots this year at Kew with the object o seeing how the relative yields of potato crops raised from eyes, chats and normal-sized seed compared. Spring had already arrived, but the necessity for no missing the growing season was realized, and therefore potato tubers were used which already showed signs of sprouting.

The method employed for preparing the eyes wa deliberately designed to be as simple as possible, s that the procedure, if successful, could be adopted by any practical person with the minimum of labour and would need no special skill or manipulation Most of the eyes on a potato are found at the 'rose end, and so the tuber is held in the left hand and thin slice or 'chip' cut off the 'rose' end with a shar knife. These 'chips' varied somewhat in size wit the shape of the tuber, but on the average they were about 1 in. in diameter, some being round others more oval in shape. The thickness of flesh was about a ¼ in. at the thickest part. When sufficient 'chips' had been accumulated they were collecte and placed, cut surface upward, on shallow trays, the bottoms of which were covered with a thin layer o peat-moss litter. The main object of the peat-moss was to prevent injury to the sprouts. The trays wer placed on shelves in a wooden seed-store room a ordinary air temperature.

It was found that after about twenty-four hours the cut surfaces had hardened and that in three o four days they had assumed a concave shape owing to shrinkage through loss of moisture. In the field experiment those 'chips' which were cut on the morning of March 24 were planted on the afternoon of March 25 and a perfect stand was obtained.

With the view of getting some idea of the length of time viability remained good, a further lot of twenty four of these 'chips' which had been stored (after twenty-four hours over the peat-moss layer) in ordinary wooden seed boxes were planted on April 3, that is, ten days after cutting. During that time they had shrivelled to about half their original size and looked like slips of cardboard. All the twenty-four 'chips' planted sprouted and grew normally. A fortnight later another small lot was planted and about 80 per cent sprouted. No special treatment was given to the soil, which was in good average condition for planting so far as soil moisture and tilth were concerned.

The variety used was the main crop 'Majestic', a well-known commercial potato. The only material available was certified Scottish seed obtained through Messrs. Carters of Raynes Park, who were also instrumental in providing the chats required from the same source.

The weights of seed used worked out as follows :

Normal war-time seed	15 cwt. per acre.
Chats for seed	6½ cwt. per acre.
Chips (eyes) *before drying*	3 cwt. per acre.

War-time seed, it should be noted, weighs heavier than normal peace-time seed (which averages about 13 cwt. per acre) as it contains a bigger proportion of out-size tubers. The 'chips' when dried weigh ess than half as much as the fresh material. In a small trial to find out the loss of weight, twenty-four rose ends or 'chips' weighed 8 oz. at the time of cutting. In twenty-four hours their weight was 7 oz., and at the end of another six days they weighed 3½ oz. In other words, the loss of weight after twenty-four hours was about 12 per cent and after a week about 65 per cent.

As the weight of fresh rose ends used for planting is about 3 cwt. per acre, the weight required after drying for a week will be about 1 cwt. In other words, one fifteenth of the weight of normal seed would be required. This is a matter of great importance in connexion with the export of potato seed for overseas countries when transport has to be considered. So far as yields are concerned, owing to limitations of land and labour it was only possible to carry out plain observation plots which consisted of three rows 96 ft. long of each kind of seed. The rows were 2½ ft. apart, but whereas the whole tubers were planted 1½ ft. apart, the chats and the 'chips' were planted 1 ft. apart. There was also a difference in depth of planting depending on the size of the planting material used ; the larger the size the greater the depth. Thus the whole tubers were planted at a normal depth of 6–7 in., the chats 3–4 in., and the chips 2–3 in. The young plants were earthed up as hey grew in the ordinary way, and on account of danger from spring frosts it was found necessary to earth the 'chips' rather sooner than the other two as the shoots appeared above ground somewhat earlier, but sprouting was very even in all the rows. The early part of the growing season was dry and cold and growth was slow. This was especially true of the 'chips', which were retarded by the necessity for early earthing up as a protection from frost, but as the season advanced these rows rapidly progressed and by the middle of July they had covered in as well as, if not better than, the other two. The plots were harvested on September 29.

The size of the plots consisted of three rows of 96 ft. × 7½ ft. or just about 1/60 of an acre each. The yields are given in the accompanying table in lb. per plot.

The crop after harvesting was put through two riddles of 1 in. and 1½ in. to separate out the tubers into three sizes.

In general the results from these small preliminary trials are promising in so far as they indicate the possibility of raising satisfactory crops of tubers from the rose ends dried into 'chips', by a simple and easily manipulated method. The results indicate that, while the yield from the 'chips' is not quite so good as it is from normal seed, yet the crop is satisfactory and better than that from chats. But it is obvious that much more needs to be done and that detailed experiment is needed to follow up this year's trials. In the first place it will be necessary to standardize the method of preparing the 'chips' for export. We still have to ascertain how long the viability of the chips can be maintained. There is also the question of dormancy in the potato. In the trials described above, seed was used which had already begun to sprout. It remains to be seen whether equally good results will be obtained from unsprouted seed. Details of planting also need further investigation. In thi, year's trials the 'chips' were planted one foot aparts but there is reason to believe from the experience gained that a somewhat wider spacing might give equally good results. Experiments are also needed in the depth of planting, and it is necessary to determine the varieties most suitable.

The chief application of this system would probably be with the Mediterranean territories, that is, Cyprus, Palestine and Malta in the first instance, although there are also possibilities in Colonies farther afield such as Nigeria and Kenya. In the Mediterranean countries the planting seasons vary. Thus in Cyprus the main crop, it is stated, is planted from August to mid-September. In Palestine the autumn planting is from mid-August to mid-September, the main planting in November and the spring planting from January to March. In Malta the spring planting is December to February, the summer planting March, and the autumn August–September.

If the seed is to be provided from Great Britain

Method	Total yield	Grading and approximate % of total yield					
		Ware		Seed		Chats	
		Weight	%	Weight	%	Weight	%
EYES— (3 rows, each 96 ft. long, 2 ft. 6 in. apart, 12 in. between sets)	526 lb.	475 lb.	90·3	33½ lb.	6·4	17·5 lb.	5·3
CHATS— (3 rows, each 96 ft. long, 2 ft. 6 in. apart, 12 in. between sets)	474½ lb.	411½ lb.	86·75	31 lb.	6·5	32 lb.	6·75
NORMAL SEED— (3 rows, each 96 ft. long, 2 ft. 6 in. apart, 18 in. between sets)	613½ lb.	558 lb.	90·96	29¾ lb.	4·84	25¾ lb.	4·20

for the August–September planting and if the tubers have to show signs of sprouting before preparing the 'chips', it is possible that an early variety of potato might be most suitable. For the later plantings, mid-season or main crop types would probably succeed. These and other details afford a fruitful field for future investigation.

Meanwhile it is hoped that it will be possible to send out small trial consignments of 'chips' to these Colonies by air or fast ship transport during the present autumn. The chief advantage of the system seems to be in the great saving in transport space and weight, and it would seem therefore to be specially applicable to the large and increasing trade in certified seed potatoes with the overseas markets.

SOME ASPECTS OF SOCIAL BIOLOGY*

By SIR WALTER LANGDON-BROWN

IT requires all one's power of sympathetic imagination to penetrate the intellectual and spiritual twilight amid which Henry VI lighted twin lamps of learning at Eton and King's College, Cambridge, following the example of William of Wykeham at Winchester and Oxford. The bright dawn of the passionate desire for learning that lighted the end of the twelfth century had faded away, the land had been devastated by the Black Death and the nation was being exhausted both materially and physically by the Hundred Years War. For nearly a century no new college had been founded at Cambridge, and Oxford was in a decline. The efforts of this saintly weakling, Henry VI, have thus proved more enduring than his father's victories and more significant than all the internecine struggles of Yorkists and Lancastrians. It is his imperishable glory to have proved the superiority of things of the mind and spirit over the clamour of battle. Well did Wordsworth say of him

"Tax not the Royal Saint with vain expense".

There is another aspect of his times which is germane to the subject of social biology. The human mind is too apt to prefer revolution to evolution. So much so that well into the nineteenth century men believed the world to have been constructed by a series of geological catastrophes. It required the labours of many geologists to prove that the principal agencies were the same as those peacefully at work to-day. Slow erosion and steady deposition of stratum after stratum have wrought more than all the volcanoes and earthquakes. Yet man still tragically retains his belief in methods of violence. But when we come to closer examination we find that, as Thomas Mann pointed out soon after the War of 1914–18, revolutions often really conceal reaction. His essay does not appear to have excited much interest at the time, but it was so prophetic in tone and so penetrating a study of German mentality that it gains fresh interest at the present juncture.

He starts by adopting Nietzsche's view that the latter part of the nineteenth century was characterize by two leading motifs—reaction masquerading a progress, and subservience of reason to emotion Though not confined to Germany they were speciall potent there. He elaborates this by maintainin under the first heading that reformations by thei very nature may have little to do with progress since they tend to re-establish the old in an extremel conservative sense, and that at a time when the new is already known, while the second arouses sympath with the chthonic and dæmonic, with night an death—in short, with a primeval and earth-bor religion. This recognition of the feeble contro exerted by the reason and intellect, and of thei incapacity to condition life, has led to scorn bein poured on reason as an unfruitful illusion, and t the reinstatement of the irrational and instinctive When reaction disguises itself as revolution, it succeed best with youth, which not being fortified by experience against such tricks, can be beguiled into accepting the most outworn devices as promising novelties The revolutionary freshness of youth has impresse upon it the "principle of mindless nature, the foll soul, hatred, war . . . the great retreat dressed ou in the uniform of the advance guard . . . Is yout really going to fall victim to this crude abuse of th new knowledge ? . . . We are no longer strangers t the disheartening sight of youthful bodies in ga quickstep, songs arising from young life, arms flun in a Roman salute, wasting the fine flight of thei youth upon hoary ideas." Since he wrote thos words, history has answered his questions. As Ker Clarkson expressed it in his "Europe in Eclipse" Hitler's "Youth Movement was his method of harnessing the challenging demands of puberty to th service of the State", while Howard Smith in hi vivid "Last Train from Berlin" concluded from stud on the spot that the Nazi "Ship of State has ridde the waves, not of the future, but of the blackes past". Hitler has completed what Wagner began—the exploitation of the myth.

The recent arrest of the veteran physiologist, Pro Lapicque, in Paris and the suppression of the *Press Medicale* are typical of much. Science, literatur and art are to be tolerated only in so far as the are within the comprehension of the autocrat. An higher values are met with the retort of Goethe Mephistopheles : "I am the spirit that denies".

Indeed, we must admit that a reactionary elemen is not uncommon in revolutions. The lictors' rod are suitable symbols for Fascism, for the Roman have been the most persistent *laudatores temporis act* in all history, even in the moments of their greates conquests. The renaissance of Irish nationalis gained force from the Celtic twilight, represente poetically by W. B. Yeats and pictorially by hi brother.

One of the most striking forms which this reactio has taken is a denial of the advantages of liberty—and that underlies much of the planning so fashionab even in Great Britain, while the other is the conceptio of the State as the supreme force. In my youth th State in England was on the whole benevolent t the individual, though like a rather inquisitive Aunt about our pocket money. It was not until I bega to travel abroad that I realized that on the Continen the State was in the main hostile to the individua Totalitarianism is no new idea, and when it is adopte the deification of the State, the divine right of king revived in a still more absolute form, is not far o Indeed, Hegel proclaimed the State as the "divine ide as it existed on earth". But when the State becomes God, it soon declares itself as indeed a Moloch, passing its own children and those of others through the fire. As social biologists we are naturally concerned to discover how things have come to such a pass, and it is somewhat disquieting to find that science has unfortunately played its part, not merely by placing powerful weapons of destruction in hands unfitted to use them, but more subtly by promulgating as facts, views of heredity which are merely theories. In the hands of pseudo-scientists this has wrought much damage.

---

* Substance of the opening address to the British Social Hygiene Council's Summer School held at Eton College during August.

Instances which will occur to anyone are the perverted use made of Darwin's phrase "natural selection" and Herbert Spencer's "Survival of the Fittest". No one stopped to inquire "fittest for what ?" and I regret that Sir Arthur Keith permitted himself to utter the palpable error that the "pruning hook of war" exemplified natural selection. At any rate, neither Darwin nor Herbert Spencer ever ruled out the idea of progress. That was left to Weismann, the Calvinist of biology as I have often called him, with his rigid delimitation between the soma and germ plasma. This denied the possibility of the inheritance of acquired characters, which Darwin to the end of his days was never dogmatic about. Hope stirred once more when mutations were discovered, only to be dashed again when it was found that the great majority of mutations were unfavourable to survival.

Meanwhile the study of variation, for which Darwin had never been able to account, underwent complete re-orientation when the Abbé Mendel's forty-year old work was rescued from oblivion. Genetics became an exact science, and it was found that man was a very variable animal. Only 9 per cent of us are obliging enough to have our greater splanchnic nerve as figured in the anatomical text-books, and it has been laid down that nothing should be labelled as an abnormality unless it occurs in less than 4·5 per cent of individuals. A 'normal' man is merely an intellectual concept; we are of an infinite variety. Moreover, to these structural variations the chemical embryologist has added many functional ones.

The time is ripe, therefore, for a full inquiry as to the inheritance of acquired characters. To do so is, of course, rank heresy, which is usually rewarded with excommunication by accredited men of science. I am therefore rejoiced to find that Prof. Wood-Jones in his little book "Habit and Heritage" has courageously dared this: first, because biologists of the past have been too exclusively interested in structure to the neglect of the moulding force of function, and secondly, because the social applications of biology have foundered on this rock more than any other. As Prof. Wood-Jones says "it is a patent fact that there has been a lowering of standards and a shrinkage of human spiritual ideals". The grafting of ridiculous claims for the application of the term 'fittest' to a certain section of the community on to the Darwinian survival thesis has gone far towards producing the sinister theories which have let loose the present demons of bloodshed and destruction. These terms, employed in the first place as purely scientific expressions, have become converted into the slogans of propaganda for acts of unthinkable brutality on a vast scale. Loud voices acclaim that it matters not if we live good lives or bad for, apart from direct disease or social degradation, we cannot hand on to our descendants any virtue or vice, any talents or degeneracies that we may have acquired during our lifetime. Consequently there was no prospect that we shall ever be able to bring about a permanent elevation of the human race by means of education and practice.

Science has broadcast the doctrine of the survival of the fittest; pseudo-science has grafted on to this pronouncement the implication that the fittest are those most red in tooth and claw. Science has broadcast the doctrine of the non-inheritance of acquired characters; pseudo-science would translate this doctrine into a thesis of racialism more cruel, more destructive of hopes of human betterment and of the attainment of international amenities than any of the other bastard slogans of our times. Therefore man inquires into the basis of the theory of such non-inheritance and finds it lacking. On the other hand, he brings forward evidence that germ cells do not possess that developmental, anatomical and physiological isolation from body cells demanded by Weismann's theory. The recent advances in chemical embryology support this proposition. The earlier stages of development are extraordinarily plastic prior to the appearance of any germ cells. This strikes at the root of Weismann's theories. But the inheritance of acquired characters in any event could only be in a very gradual process, and cannot yet be regarded as proved.

It would not be just to ascribe all the disastrous deterioration in moral values to mishandling of the biological theories. Certain philosophers and especially Hegel must take their share of the blame. When we inquire into the validity of the claim for "the biological necessity of war", it is interesting to learn what light the newer psychology has to throw on the subject. We shall at once be told that aggressiveness is deeply inherent in human nature, but it is repressed by society until it becomes so intense that it can find an outlet only in warfare. But when we ask what is the origin of this aggressiveness we are given two diametrically opposite answers.

Thus Freud attributed it to the persistence of childish hatred against parents, brothers and sisters which he regarded as our most fundamental impulse. He maintained that social feelings arise as a superstructure founded on these jealousies and rivalries, and thus the hatred we repress with difficulty remains the mainspring of our corporate life. His own feelings are displayed in his statement that "the masses are both lazy and stupid, and their ingrained laziness will not be removed by kindness but only by leadership prepared to use appalling force . . . One cannot deny the grandeur of this project". Well, his nation have experienced this since those words were written, but "the grandeur of the project" is perhaps beginning to lose its appeal.

On the other hand, Ian Suttie, who was trained in the Freudian School and used its methods for years, concluded that aggressiveness originated from the thwarting of primary natural love. Dr. Ranyard West in his interesting study of "Conscience and Society" says that Suttie puts forward the biological and individual role of the nourishing and protective mother and the sociological reactions which may result from her place in life as opposed to those of Freud's threatening father. Thus for Suttie the germ of society is a band of brothers and sisters gathered under a mother, as opposed to Freud's brothers banded in hostility against a father. I might interpolate here that it is, of course, quite possible for a matriarch to imitate Freud's conception of a father. I recently read Harold Nicholson's "Life of Hamilton

Rowan", whose dominating mother was the mainspring of his rebelliousness throughout his life, despite his frequently expressed desire to please. West goes on to say that the reactions of Suttie's patients were different from those of Freud because the personalities, the mental adherences and the faiths of the two analysts diverged.

Now if two astronomers working with similar telescopes at Greenwich and in Cape Town gave different times for the rising and setting of the moon they can both be right, the difference being due to their different positions on the globe. But psychologists are not observing through telescopes; they are observing human beings through their own minds which are deeply coloured by their own experiences. In the same way, a portrait, unlike a photograph, tells us much about the man who painted it.

Now this divergence between philosophers is no new thing. Nor is totalitarianism a new idea. It was first proclaimed by Thomas Hobbes in the seventeenth century. Although he was born in the year of the Armada and lived nearly up to the time of our Revolution in 1688, thus seeing great changes, he never altered his view that men were all selfish and aggressive, each against his fellows in a life that was "nasty, brutish and short". "So in the nature of man," said he, "we find three principal causes of quarrel—competition, diffidence and glory. The first maketh a man to invade for gain, the second for safety and the third for reputation". Thus war was the natural state of mankind and "force and fraud are in war the two cardinal virtues . . . Covenants without swords are but words and of no strength to secure a man at all." In that last respect he would find more to agree with him now than in the nineteenth century!

Yet the physician-philosopher, John Locke, who lived through the most disturbed part of the same century (as he said "I no sooner found myself in this world than I found myself in a storm") differed from Hobbes in precisely the same way that Suttie differed from Freud. He believed that a demand for social love and approval from his fellows was the primary emotion in man. He averred that he who "declares himself to live by another rule than that of reason and common equity [committed] a trespass against the whole species". Ranyard West's comment is "in contrast with Hobbes, Locke's state of nature is in fact a state of good nature . . . Where Hobbes sees anarchy unless men give up self-government, Locke sees a natural community which will improve its condition by careful self-government and run no risk in the process". To-day it is of special interest to read of this controversy of nearly three centuries ago between two opinions which hold the field to-day.

Now it is significant that Hobbes had a violent father and Locke had not. Hobbes' mother had such a dread of the Spanish Armada that he was born prematurely. As he put it long afterwards, "She brought forth twins—myself and fear". A brutal father and a terrified mother bred in the son a gloomy totalitarian philosophy which had an unfortunately wide influence.

Indeed, in view of the tremendous influence of our early upbringing, it is not surprising how frequently philosophers and psychologists who regard hate as the strongest motive had unkind or even brutal fathers, while those who put love in the first place had affectionate mothers.

What is true of these learned men is of general application. It adds new force to the recognized vital importance of the home; it adds tremendously to the responsibility of parenthood. It is well known what a large proportion of neurotics and criminals come from 'broken homes'. There are plenty of instances of totalitarian leaders having an unhappy childhood.

The fatal flaw in Hobbes' premises was that he regarded human beings as isolated individuals *in vacuo*, whereas inescapably the earliest social group is the family, and the reaction of the individual to that group determines much of his future outlook on the whole of his subsequent life. As a medical man I am profoundly impressed with the truth of this. Let me take what may seem a trivial illustration: the myth of Santa Claus. Here is a boy who determines to find out about it and soon discovers who plays the part of that Christmas visitor. He is not capable of realizing that this is merely the mythical expression of an encompassing parental love, and later on may reject the symbolism of the Book of Genesis—at least until he is over forty. His sister may suspect the identity of Santa Claus, but may close her eyes to it, clinging longingly to the idea of the nocturna visitant with his reindeer sledge. Later on she wil be equally ready to close her eyes to anything which she fears might shake her rather timorous faith.

I have on a previous occasion urged the importance of a boy's reaction to his first realization that his hitherto thoughtless cruelty is wrong. I am sure from the histories I have often obtained that this is an almost universal and dramatic experience. It has been beautifully related by Frank Kendon in his delightful book "The Small Years". If cruelty is persisted in after that, what has been almost natura behaviour assumes a new significance, and the seeds o sadism are sown. "For without the law sin was dead . . . but when the commandments came, sin revived".

Of the tragic results of both bad heredity and bad early environment in exalted circles, one could scarcely find a more striking example than the founder of Eton College. Henry VI succeeded hi father when only nine months old. Henry V was no mere swashbuckler; he had a strong sense o justice and was fond of music and literature. So fa so good, but his mother's stock was bad. With such heredity and an unfavourable environment it is no surprising that he had a complete mental and physica breakdown when he was thirty-two. The loving meticulous care he devoted to his two foundations which he initiated when only eighteen, gave promis of a happier career had he not been doomed from th cradle by a thoroughly evil family environment.

It has been well said that heredity determine what we can do and environment what we do do. The trouble with eugenists is that they are not alway clear what their aim is—whether for brain or brawn. Certain it is that a biological inferiority may b consistent with genius. Turner's defective eyesigh was utilized by him to create gorgeous visions, many immortal works have been produced by the tuberculous, and Beethoven's hereditary otosclerosis did not prevent his reaching supreme heights in musica composition.

Carr-Saunders has recently reminded us that w find it more attractive to think of mastering ou surroundings than of mastering ourselves. Th pioneer efforts of Galton in the latter direction were weakened by his conventional class consciousness and lack of appreciation of social problems; still true was this of some of his disciples. Consequently professional biologists stood rather aloof, and indeed until the re-discovery of Mendel's work lay bare the mechanism of inheritance, eugenics could scarcely claim to be a science. The obstacles in the way of making a genetic analysis of man are immense, but apparently the results obtained so far do not clash seriously with Galton's intuitive conclusions. We must remember that inheritance merely means that offspring get their genes from their parents, while environment includes for man not only physical factors, as for all animals, but also the provision of opportunities for learning.

The object of social organization is not standardization, but the creation of conditions under which genetically unique individuals (which we all are) can best fulfil the promise that is in them. Unfortunately there is reason to suspect that the genetic material in a civilized society deteriorates slowly, but almost certainly, for harmful mutations are preserved which would perish under cruder conditions. True, they are compensated for, but that is not cure, and their persistence must be injurious to the common stock. There are always some people of subnormal mentality and physique who cannot hold their own in the circle in which they were brought up and who therefore tend to sink. The damage is enhanced by the inverse relation which exists between social class and fertility, even though this is now on the wane, except in the lowest group of all. In the other strata the average of intelligence does not vary greatly. But the danger of unfavourable mutations occurring and being encouraged to persist Carr-Saunders regards as insidious, for there is a not inconsiderable element in the population which by reason of inferior hereditary endowment cannot take advantage of a good environment.

Biology can be a useful corrective to the machine-minded planners who are running riot to-day, for man is not a robot. We start with the initial advantage that children are all intensely interested in the manifestations and origins of life—sometimes to the confusion of their more conventionally minded elders. Though of recent years motor-cars, aeroplanes and radio have claimed an increasing amount of their attention, there are few who do not, if they can, keep some kind of domestic pet, occasionally of a somewhat exotic type. It would be a real disaster if education were so directed as to suppress this interest in living things instead of using it as the basis for learning something about man's place in the universe among other forms of life.

On one hand it seems illogical to separate scientific questions from their application to human affairs, while on the other hand it is absolutely essential that there should be complete freedom in scientific research. Yet at the moment there is a decided movement to place research under State control. Liberty seems to be a demoded ideal. We may legitimately inquire how it can be determined at the outset of a research what its practical benefits will be. What we do know is that most of the great scientific discoveries have been made by men actuated simply by a thirst for knowledge. As Prof. Starling said, all knowledge faithfully pursued for its own sake ultimately yields useful results. Thus one of my teachers, W. H. Gaskell, researched on the rhythm of the heart and on the sympathetic nervous system without any thought or even interest in possible clinical applications. It was not until several years later that this work became the basis of newer conceptions of heart disease and of the effect of the emotions on the state of the viscera.

Biology can bring valuable information and advice to the statesman, if the evidence is objectively criticized by those scientifically trained, but if controlled by politicians it rapidly deteriorates into a fallacious guide; a blind leader of the blind. Indeed, we know that with the best will in the world it is extraordinarily difficult to remain sufficiently objective if we start a research for the purpose of establishing a preconceived hypothesis. I gave up laboratory research myself partly because I felt that difficulty was too great for me. The goal of clinical research, on the other hand, is pre-ordained—the healing of the patient. Politics, being in its essence tendentious, cannot control objective science without disaster. The converse aid which biology can render to statesmanship is admirably indicated in Dr. K. E. Barlow's admirable little book "The Discipline of Peace". He bases his appeal on the broadest biological grounds. He insists on the inexorable interdependence of soil, vegetation and animal life, pointing out in no uncertain tones the failure of the industrial age to observe it and the grave consequences thereof. In an interesting way we are led from a consideration of the building up of fertile soil by vegetable life to the building up of potential energy through photosynthesis by plants, which provides for the kinetic activities of animals, combined with the reverse process by which animal and vegetable waste products are utilized. The facts are well known, though not, as he shows, always acted upon. But the point he emphasizes is that each of these entities is obliged to follow its own discipline, and that interference by man can and does disastrously upset the balance. Deforestation, often merely to supply newsprint, and agriculture pursued to yield immediate returns regardless of the future, are rapidly reducing large areas of previously fertile land to dustbowls or swamps. Industrialization has led to excessive raids upon Nature to supply the machine, and the products of those machines have in turn to be bartered for yet more products of the soil. Moreover, it has led to aggregation of population into towns, thus simultaneously increasing the demands on Nature while diminishing its yield. Man must cease to be a bandit of the soil and in turn observe his own discipline, which he can do only by the free exercise of his intelligence. If we want to build a world in which men can live at peace, we have no choice but to pass to a new era in which man must concern himself with the balance and harmony of life. The whole thesis is convincingly worked out to show that while physics may increase our material comforts (or we might add, pave the way to new disasters), only biology can be the scientific guide to a true way of life.

In conclusion, may I suggest that all of us as teachers can gain inspiration and refreshment from Sir Charles Sherrington's short book on "Life's Unfolding", traced from the synthesis of the protein molecule, through the microscopic cell, on to an "organized life-system centred upon itself". Here it is interpreted by a master of science who also has the mind of a philosopher and a poet. He reminds us that wonder commonly vanishes with childhood. The wonderful is taken for granted, so as to enable us to get on with life. Much later, when life's pace is slackened, wonder may return. Wonder, then, is the mood in which he invites us to approach his subject; and it is indeed a wonderful re-telling of the story, vivid and yet accurate in its details. One is reminded of a picture which, having become dulled in colour, is restored to its pristine freshness by a skilful hand. Take, for example, the description of the great adventure by which marine animals adapted themselves to a terrestrial existence and yet still carry the salt of the archaic sea in their internal economy. Avoiding anthropomorphism in his discussion of 'higher and lower' forms of life, he still claims that range of dominance of the environment is a feature to which the term 'higher' can be accorded. Since mind is one of the great keys to this dominance, the term is almost graded by degrees of mind. At the present time, man is, as regards conquest of his surroundings, the most successful of all living forms. On that ground we can acclaim him the highest of all living forms.

It is towards greater control over that environment, which also involves greater control over ourselves, that the lessons of biology and all its application should lead. For in the wise words of Plato, "Civilisation is the victory of persuasion over force".

HENRY TRIMEN, F.R.S. (1843-96)

By T. E. T. BOND
Tea Research Institute of Ceylon

HENRY TRIMEN was born in Paddington, London, on October 26, 1843. He received his education at King's College School (then in the Strand) and even as a schoolboy showed an ardent liking for natural history, beginning to form a herbarium and frequently visiting the Botanical Department of the British Museum to determine his collections. As with so many others of those days, he found his best opportunity of receiving further biological training lay in the study of medicine, and from school he entered the Medical College at King's in 1860, graduating M.B. with honours in 1865. After graduation he held for a short time an appointment as medical officer during a cholera epidemic in the Strand. But already it was clear that his main interest lay in the field of systematic botany. For this subject he was exceptionally well endowed with a natural ability for thorough and accurate observation and with a strong interest in historical studies, while his work throughout was characterized by a breadth of outlook to which his medical background made no small contribution.

As an amateur botanist, Trimen had already made a name for himself by adding to the British flora our smallest known flowering plant—the duckweed *Wolffia arrhiza*—and he had also taken an active part in the proceedings of such bodies as the Society of Amateur Botanists (now defunct) and the Botanical Exchange Club. Official recognition soon followed in his appointment, in 1867, as lecturer in botany at St. Mary's Hospital Medical School and, two years later, as assistant in the Department of Botany at the British Museum. His position now gave full scope to his abilities and he applied himself actively to his chosen fields of interest. In systematic and topographical botany, his best-known early work was the "Flora of Middlesex", projected as a joint publication with his former school-fellow Dyer (afterwards Sir W. T. Thiselton-Dyer) and completed in 1869. Several other papers followed, including critical studies of British species of Polygonum, Rumex, etc. His work in the interests of the botanical community in general was of no less importance and included the arduous task of editing the *Journal of Botany* for nearly ten years. He took an active part also on the council of the Linnean Society of London, of which he had been a fellow since 1869. Finally, mention must be made of the notable series on "Medicinal Plants", undertaken in collaboration with Prof. Bentley, and published in instalments from 1875 onwards. Trimen's contributions to British botany were brought to a close in 1879, on his departure for Ceylon to become director of the Royal Botanic Gardens, Peradeniya.

In Ceylon, Trimen will always be remembered as the author of the monumental "Handbook to the Flora of Ceylon". This work, dealing with nearly 2,800 species of flowering plants in more than a thousand genera, was planned on a generous scale following the arrangement of the "Flora of British India". It was the result of much preliminary research into the Island's flora and the history of its investigation, from the work of Hermann in the seventeenth century and the publication of Linnæus's "Flora Zeylanica" in 1747, to the appearance of Thwaites' "Enumeratio" in 1864. The first volume of the "Handbook" appeared in 1893 and the author himself completed two more volumes in his life-time, covering the dicotyledons from the families Ranunculaceæ to Balanophoraceæ, inclusive. The remaining families of dicotyledons, with the monocotyledons and cycads, were covered in two more volumes by Sir J. D. Hooker, working in part from Trimen's notes. The Flora, thus completed in five volumes by 1900, was revised and extended in A. H. G. Alston's supplementary volume issued in the same format in 1931.

Trimen's work for Ceylon botany in its widest aspects was not confined to the systematic examination of the country's flora: his labours are also commemorated to no small extent in the comprehensive collections and spacious arrangement of the world-famous Gardens of which he was the director. In his official capacity he also took a prominent part in developing the Island's important tea and rubber planting industries, and in introducing many of its fruits and other exotic agricultural products. He retained all his old interest and pleasure in the society of other botanists, and from time to time welcomed to Peradeniya such eminent visitors as F. O. Bower, K. Goebel, G. Haberlandt, M. C. Potter, J. B. Farmer, F. W. Keeble, and others. In fact, while on leave in England in 1886, he was in part instrumental in obtaining from the British Association a grant towards equipping a laboratory at Peradeniya at which British and other visiting botanists were provided with facilities for their work.

Trimen died on October 16, 1896, having returned to Ceylon from leave in the previous year, against the entreaties of all his friends. He had by then become totally deaf and was also paralysed in one leg. He died, as he had lived, in single-hearted devotion to his work, almost his last moments of consciousness being occupied with attempts to write a few notes in continuance of his "Flora". His end has been most movingly described in the memoir by James Britten in the *Journal of Botany* for that year. In the country of his adoption, Trimen's early death was felt alike as a great loss to tropical botany and as the passing of a friend to all sections of the Ceylon public. Of him it could be said, in the words of the writer of a later commemorative article published in the Ceylon *Tropical Agriculturist*, that "a more obliging official, more attentive correspondent, or more pleasant friend and genial man than Dr. Trimen never came to Ceylon".

OBITUARIES

Prof. J. M. Macfarlane

PROF. JOHN MUIRHEAD MACFARLANE, emeritus professor of botany in the University of Pennsylvania, died at his home in Philadelphia a few weeks ago. He was born in Kirkcaldy in 1855, and his work was over more than twenty years ago. One or two old friends still remember him when he and they were boys in Edinburgh, where he learned his botany from "Woody Fibre" and from Alexander Dickson, and became one of Bayley Balfour's first assistants. It was under Balfour's influence that he wrote his once well-known paper on the minute structure of plant hybrids, which remained perhaps his chief work to the end. It was a careful comparison, within the histological limitations of its day, between the tissues of various hybrids and their parents, in such curious cases as the so-called *Philageria* (that is, *Lapageria* × *Philesia*) *Veitchii*, and the famous 'graft-hybrid', *Cytisus Adami*. This investigation led to his first appointment in the University of Pennsylvania in 1892, and gained him the Banksian Medal of the Royal Horticultural Society a little later on. His old master Dickson had been interested in pitcher-plants, and the Edinburgh Garden was rich in these, including the rare little Cephalotus and many hybrid Sarracenias and other things. Macfarlane had a note in NATURE on honey-glands in pitcher-plants, nearly sixty years ago. Long afterwards he did the pitcher-plants for various Floras, including those of British North Borneo and of New Guinea, and he wrote the chapters on Nepenthes, Sarracenia and Cephalotus for Engler. He was a very faithful and a very industrious man.

D'ARCY W. THOMPSON.

Capt. R. D. Williams

CAPT. R. D. WILLIAMS, officer in charge of clover breeding and other investigations at the Welsh Plant Breeding Station, died very suddenly while on advisory work in Carmarthenshire on October 7. He was fifty-four years of age and had been a member of the Welsh Plant Breeding staff since October 1920. His genetical work on *Trifolium pratense* in particular is well known through papers published in the *Journal of Genetics* and elsewhere, while on the more immediately practical side the Aberystwyth strains *S*.123 red clover, *S*.100 white clover and others bred by him are already grown and appreciated in Great Britain.

WE regret to announce the following deaths:

Dr. Edwyn Bevan, O.B.E., F.B.A., lecturer in Hellenistic history and literature in King's College, London, during 1922–33, on October 18, aged seventy-three.

Dr. W. H. Hatfield, F.R.S., technical research director of Thomas Firth and John Brown, Ltd., on October 17, aged sixty-one.

Sir Michael Sadler, K.C.S.I., C.B., formerly master of University College, Oxford, and, during 1911–23, vice-chancellor of the University of Leeds, on October 14, aged eighty-two.

Prof. Pieter Zeeman, For.Mem.R.S., formerly professor of physics in the University of Amsterdam, aged seventy-eight.

NEWS and VIEWS

British Drug Houses: Dr. Francis H. Carr

REFERENCE was made in NATURE of October 16 to the resignation of Mr. C. A. Hill as chairman and managing director of British Drug Houses, Ltd. Dr. Francis H. Carr has succeeded him as chairman of the firm. Dr. Carr has had wide experience in the fine chemical industry. He was educated at Whitgift School and Finsbury, where he was one of the first holders of a Salters Company's fellowship. He started his practical experience with Burroughs Wellcome, working with them during 1898–1914. He was with Messrs. Boots at Nottingham during the War of 1914–18 when he took an active part in producing for the first time in England certain chemicals which had hitherto been a foreign monopoly. In 1919 he joined British Drug Houses, Ltd., and has done his full share in bringing that company to its present eminence. Apart from his active business career as a technical chemist, Carr has been a leader in all that concerns the progress of chemistry in the outside world and unsparing in his efforts to put the profession on a high level. He has served as chairman of the Association of British Chemical Manufacturers and president of the Society of Chemical Industry, and has been active in innumerable other ways known to his colleagues.

Gift to the Royal College of Surgeons of England

THE destruction of the greater part of the historic Hunterian Museum of the Royal College of Surgeons of England by enemy action in May 1941 was a grievous loss of a national treasure house. This loss, however, has been a spur to the College to build up a worthy successor of the old collection. From the first it was determined that its Research Department, engaged in fundamental research work necessary for future surgical progress, should not be hampered in its work. This decision was followed immediately by a generous gift from the Bernard Baron Trustees to endow the chair of experimental surgery and so release general College funds for the reconstruction work. Now, when plans are being made for the restoration of the Museum, comes the news that two further gifts each of £100,000 from Mr. W. H. Collins have been made to endow the Departments of Human and Comparative Pathology and of Human and Comparative Anatomy. One of these gifts, that to the Pathological Department, is to be immediate, the other to mature after the death of the donor.

Mr. Collins in his letter announcing the gift to the president of the College, Sir Alfred Webb-Johnson, wrote: "Throughout my career I have realized how essential is the study and investigation of basic problems. Success of armies in the field is dependent on careful planning and preparation at headquarters, and victories in the war against disease can only be achieved by due application and increased knowledge of the fundamental medical sciences". No better dedication of a gift could be written and no better purpose could be served than to encourage the patient labours of those who lay surely the foundations on which others build. It is significant too that the donor expresses the hope that "the gifts will enable the Council to proceed with confidence with their responsible task and to engage the services of men of outstanding ability to assist them in their labours". In the post-war world of medicine in Great Britain the College will indeed have a unique place. Apart from its primary task of testing the fitness of those who aspire to practise the art and advance the service of surgery, it will have a special function in providing a link between the laboratory sciences and the treatment of the sick. Perhaps, too, in the future it will aspire to develop a hospital where discoveries at the laboratory bench will become quickly the triumphs of the hospital ward, and where the perplexing problems of disease will be brought rapidly to the attention of the laboratory worker. Cross-fertilization of ideas between laboratory and ward has already, in the association of the Rockefeller Hospital with the Rockefeller Institute in New York, produced advances in the science of medicine which have been of lasting benefit to suffering humanity.

Mr. Collins has been for many years a generous benefactor to hospitals in Great Britain, but his latest gift, far from benefiting but a few hospitals, will help to provide that new knowledge which is the free gift of medical research to all mankind.

Preservation of Museums in Italy

REPLYING to questions in the House of Commons, Sir James Grigg, Secretary of State for War, stated that an adviser is being appointed to deal with archæological questions such as measures for the protection and conservation of ancient monuments and works of art in countries occupied by British troops. Meanwhile British and American experts are already in occupied territory engaged in the supervision and protection of ancient monuments, museums, etc. The British officers sent or provisionally selected are from the British Museum, Inspectorate of Ancient Monuments (Ministry of Works), National Gallery and the Royal Institute of British Architects. Lists of æsthetic and ancient monuments have been prepared in Great Britain, and detailed instructions supplied to these officers regarding closing, guarding and, where necessary, repairing museums and similar institutions. Italian curators and their staffs, where suitable, are to be retained. In this connexion it is interesting to read Dr. G. B. Bidder's letter in *The Times* of October 14, in which he states that the aquarium in the Villa Nazionale of Naples, and so presumably the famous Stazione Zoologica Internazionale, is safe. Dr. Bidder adds that so lately as last August, the director, Dr. Reinhard Dohrn, was still in charge of the Station.

Anthropological Aspects of the Origins of War

A STUDY of the origin of war and its various manifestations from an anthropological point of view, by J. R. Swanton, of the Bureau of American Ethnology, which has been issued by the Smithsonian Institution in the War Background Studies series (No. 12), indicates the impossibility of separating the consideration of wars between tribes or nations from disturbances internal to them. Reviewing the various motives which lead to war and comparing warfare in simple and in advanced societies, Mr. Swanton emphasizes the relations between motives governing the individual and those which result in collective hostilities. These and further considerations of group controls, international relations, the effect of warfare upon trade and the place of the military establishment in the national life, lead to the conclusion that war is an expression of man's anti-social tendencies; and just as individual and collective crimes have to be controlled within the State by men trained and equipped to meet them, so the destructive threat represented by foreign armed forces when used for aggression must be countered by armed forces prepared to meet them. Between many nations there is a constantly increasing tendency to settle differences by peaceful means, and if these areas of law and of good feeling continue to spread, the preservation of order will pass more and more to the police, or to armed forces acting in that capacity. Consideration of the origins of war and attitudes towards it among different people shows that collective pugnacity is an acquired trait—cultural not biological. Fear and not hatred is the underlying if not the dominant motive, and when this fear can be allayed, belligerency will disappear with it. There is no mystery about the force required to terminate warfare. All that is needed is the will to do so.

A National Administrative Staff College

A SHORT statement, "A National Administrative Staff College", has recently been issued as a contribution to discussion by the members of a group which during the past twelve months has been studying this topic (honorary secretary, N.A.S.C., Norwich House, Southampton Place, London, W.C.1). The proposal is to found such a College to investigate and to expand the technique of organization and administration in civil life. To it will be admitted men and women aged about 28–34 who have shown ability and capacity in their particular spheres, including not only Civil servants, but also local government officers, men from industry and commerce, trade union officials and members of trade associations and professions such as medicine, the law, the Church and education. In addition to training such executives, the College will aim at promoting a better understanding of the inter-relation of the activities of the organizations from which its students are drawn, and it should also provide a centre for research into all aspects of administration. The curriculum will include a close study of the fundamental principles on which sound administration must be based, and an introduction to the many disciplines of which students must make use in their subsequent work. The whole course will emphasize the responsibility of leadership and the importance of correct practice in dealing with the central issue of human relations. The College will also endeavour to nourish the other qualities required in a leader—moral courage, judgment, energy, imagination. Probably not more than a quarter of the time will be devoted to formal instruction, and the fullest use will be made of modern methods such as the 'case' method. Fees per student would be about £30 per month, including living expenses and tuition. The group has already in draft a memorandum and articles of association, and is prepared to incorporate the College and to form an initial court of governors.

Eratosthenes and the Circumference of the Earth

In *Sky and Telescope* of September, under the heading "Saluting an Astronomer", Joseph R. Habes has an article which describes the method adopted by Eratosthenes for measuring the circumference of the earth. He knew that the sun threw no shadow at the summer solstice at Syene (the modern Assuan) and at the same hour at Alexandria the pointers of the sundials threw shadows, because Alexandria is north of Syene. He found that the arc of the shadow in the hemispherical bowl of the sundial was 1/50 of its circle, and hence concluded that the arc of the earth between Syene and Alexandria, which was 5,000 stadia, was 1/50 of the great circle of the earth. By this means he found that the circumference of the earth was 250,000 stadia, according to Cleomedes, but Strabo says that it was 252,000 stadia. A discrepancy arises when we come to consider the length of the stadium. The Greek stadium was 606·75 ft., and if Eratosthenes used this he was obviously very much in error in his computation. On the other hand, Pliny in his "Naturalis Historia" claims that Eratosthenes made 40 stadia equal to the Egyptian *schoinus*, and if this be so, taking the *schoinus* as 12,000 royal cubits of 0·525 metres each, the length of the stadium was 516·73 ft. If we accept the account of Strabo that Eratosthenes measured the circumference of the earth as 252,000 stadia, the circumference would be 24,662 miles, and the polar diameter 7,850 miles—only 50 miles short of the true polar diameter. This is considered to be one of the first great triumphs of scientific calculation.

Association of Scientific Workers : Scientific Film Group

In view of the rapid increase in the applications of photography in science and industry, the West Midland Area of the Association of Scientific Workers has formed a Scientific Film Group. By means of lectures, exhibitions and news letters containing abstracts of recent publications, the Group will provide information for scientific workers using photographic techniques in industrial processes and research laboratories. The Group will also foster interest in the manifold applications of photography. It has already set up an information service able to provide expert advice on all·aspects of photographic technique. The Group will endeavour to meet the demand of the general public for good-quality scientific films covering the whole field of science and technology. Monthly film shows will be held in Birmingham throughout this winter. The first show will take place in the middle of November. In the future the Group intends to produce original films and photographs. Applications for membership and inquiries should be addressed to Mr. H. Zerkowsky, Rowney Green, Nr. Alvechurch, Worcs.

Early Scientific Works

Catalogue 8, recently published by Davis and Orioli of 1 St. Martin's Street, Wallingford, Berks, contains a collection of 143 items printed before 1500. In addition to works on theology, philosophy and literature, heraldry and cookery, science and medicine are presented by the following works, among others : Albertus Magnus, "De secretis mulierum" (*c.* 1500) ; Aristotle, "De numero Partium" (*c.* 1490) ; Bartholomoeus Anglicus, "El libro de proprietatibus" (1494) ; Capillutus, "De curatione pestiferorum" (*c.* 1487) ; Celsus, "De medicina" (1497) ; Decembrius, "De Genitura Hominis" (*c.* 1495) ; Mesue's "Opera Omnia" (1497) ; Savonarola, "Practic in Medicina" (1498) and Silvaticus, "Opus Panectarum Medicinæ" (1498).

Announcements

Dr. B. A. Keen, assistant director at Rothamsted Experimental Station, will be absent from Rothamsted for approximately twelve months, acting as a scientific adviser to the Middle East Supply Centre, Cairo. He will report on the scientific and technical problems and resources (including personnel) in the area, and make recommendations on the establishment of a suitable organization, in the Middle East and elsewhere, to ensure the fullest practicable service of information and advice, with special reference to the post-war period. Dr. Keen will deal with agricultural resources and development and related problems, including education. He will be accompanied by Dr. E. B. Worthington, who will examine various non-agricultural matters. An American representative is expected to join the mission at a later date. The countries to be visited extend from Persia to Libya and from Turkey to the Sudan. It is hoped that the mission will be able to report by November 1944.

The following appointments and promotions in the Colonial Service have recently been made : P. S. Hammond, agricultural superintendent, Gold Coast ; D. K. McEwan Kevan, agricultural officer, Kenya ; W. V. Rose, agricultural officer, Nyasaland ; R. O. Williams, agricultural officer, Kenya ; H. B. Atkinson, inspector of plants and produce, Gold Coast ; G. G. Robinson, entomologist, Medical Department, Northern Rhodesia ; N. S. Stevenson (conservator of forests, British Honduras), conservator of forests, Nigeria.

The following appointments in the University of Sheffield have recently been made : Dr. A. I. G. McLaughlin (H.M. medical inspector of factories), honorary lecturer in industrial medicine in the Department of Public Health ; Mr. P. E. H. Howarth and Mr. R. E. Peasegood, temporary demonstrators in anatomy ; Captain J. H. Hale, assistant bacteriologist and demonstrator in bacteriology ; Dr. Enid Bankier, demonstrator in zoology to medical and dental students ; Mr. W. Davies, research assistant in refractory materials (in addition to his duties as temporary part-time assistant lecturer in geology).

The British Association of Refrigeration, at its forty-fourth annual meeting, has decided to change its title to the Institute of Refrigeration, the change to take place on March 26, 1944. At the same time, the Association will establish a qualified class of technical membership attainable by examination on the lines of the major engineering institutions.

R. J. Braidwood has issued as a reprint from the "1943 Britannica Book of the Year" notes describing recent archæological work in Iraq, Palestine, Kenya, Morocco, England, etc. The notes form an excellent and useful three-page summary of British war-time discoveries and publications in the realm of prehistory.

Relation of Nucleotides and Nucleosides to Proliferation-Promoting Factors produced by Ultra-Violet Irradiated Yeast Cells

Recent reports by Loofbourow[1] on the role of adenine nucleotides in wound hormone preparations from ultra-violet treated yeast cells prompt us to give a preliminary account of some of our experiments which bear upon the problem.

Adenine compounds were demonstrated to be present in the wound hormone preparations in the earliest studies[2], and the presence of guanine, although in smaller amounts, was also indicated[2]. On the basis of spectroscopic and chemical evidence, it was suggested that the purines were present in nucleic acid-like form, that is, as nucleotides. These findings were confirmed by Davidson[3] who showed the presence of purine nucleotides and nucleosides. Davidson also found a large amount of amino nitrogen. We demonstrated the importance of known yeast growth factors and amino-acids in the wound hormone preparations but showed that additional factors were also involved[4]. Loofbourow confirmed these findings[1].

In the present experiments, adenosine, guanosine and two samples of yeast adenylic acid were assayed alone and combined in concentrations up to 10 γ per ml. for their effect on the 24-hour yeast crop (*S. cerevisiæ*), using the previously employed[4] rocker-tube technique and Williams' medium[5] supplemented with inositol, thiamin, biotin, calcium pantothenate, pyridoxin, riboflavin, uracil, choline, acetylcholine, ethanolamine and nicotinic acid, as previously described[4], but substituting a casein hydrolysate for the amino-acid supplement. The nucleosides and nucleotides were also assayed in the presence of various amounts of a cell-free fluid from ultra-violet injured yeast suspensions. This fluid was prepared by washing 1·5 lb. of Fleischmann's bakers' yeast with 3 litres of distilled water, centrifuging, and resuspending in distilled water added gradually to a volume of 6 litres. The suspension was irradiated for 96 hr. with a quartz mercury arc during stirring and with the maintenance of constant volume. The suspending fluid was separated by centrifuging, followed by Buchner and Berkefeld filtration, and autoclaved, after which it was concentrated to convenient volume *in vacuo* and sterilized by autoclaving. Results of typical assays are shown in the accompanying table.

EFFECTS OF NUCLEOSIDES, NUCLEOTIDES AND 'WOUND HORMONE' ON GROWTH OF YEAST IN SUPPLEMENTED WILLIAMS' MEDIUM

24-hr. yeast crop, mgm. (dry wt.) per ml. (initial seeding, 0·03 mgm.).

Added substance (10 γ per ml. each)	Without wound hormone	With wound hormone	
		8·8 γ per ml.	140 γ per ml.
Medium alone (control)	1·05	—	—
Adenosine ($3 \cdot 7 \times 10^{-5}$ *M.*)	1·14	1·30	1·84
Guanosine ($3 \cdot 5 \times 10^{-5}$ *M.*)	1·11	1·32	1·66
Adenylic acid, I ($2 \cdot 9 \times 10^{-5}$ *M.*)	1·08	1·35	1·79
Adenylic acid, II ($2 \cdot 9 \times 10^{-5}$ *M.*)	1·04	1·35	1·75
Adenosine plus guanosine	1·41	1·53	1·73
Adenosine plus adenylic acid, I	1·33	1·47	1·79
Adenosine plus adenylic acid, II	1·36	1·44	1·79

Yeast nucleic acid (8 γ per ml.) was also tested but it was without effect and is not included in the table.

It is seen that adenosine possesses growth activity and yeast adenylic acid does not, confirming Loofbourow[1]. In addition, guanosine also possesses activity. Combination of adenosine with guanosine gives greater activity, as might be expected, but combination of adenosine with essentially inactive adenylic acid also gives increased activity. Addition of the wound hormone preparation, even in concentrations of the same order as the added nucleosides and nucleotides, produces additional growth. This probably means simply that optimum concentrations of the active substances were not present in the experiments reported and work is under way to ascertain whether this is so. The growth activity of the nucleosides accords with the finding of Englert[6] that yeast nucleic acid, normally inactive, acquires growth activity after subjection to alkaline hydrolysis.

Manometric studies were made, using 4 mgm. (dry wt.) of yeast per flask and adding the wound hormone preparation in quantities of 0·125–1 mgm. per ml. and the other substances in concentrations of 0·03–0·25 mgm. per ml. The wound hormone preparation caused a slight stimulation of oxygen uptake of yeast (10–20 per cent at the end of 1 hr.) in $M/15$ KH_2PO_4 containing 0·02 per cent glucose and in the supplemented Williams' growth medium, confirming an earlier observation[4]. The respiratory quotients, however, were lower than the control, even though the carbon dioxide output was raised in the latter medium. This appears to differ from Loofbourow's finding[1], but experimental conditions were probably different. The samples of yeast adenylic acid very slightly stimulated respiration in both media but did not raise carbon dioxide output in phosphate and raised it only slightly in Williams' medium, so that the R.Q. (respiratory quotient) was slightly lowered. Adenosine and guanosine had a slightly depressing effect on both oxygen uptake and carbon dioxide output in phosphate and caused a slight lowering of the R.Q. In Williams' medium both oxygen uptake and carbon dioxide output were stimulated somewhat, with the R.Q. scarcely affected in the case of guanosine and slightly raised in the case of adenosine. Yeast nucleic acid was essentially indifferent. All metabolic effects were relatively small. The R.Q.'s in phosphate on the whole were slightly above 1, while in Williams' medium, with an abundance of sugar, they usually ran in the neighbourhood of 6–7. We have shown previously that the oxygen uptake of our yeast is relatively unaffected by most of the bios components and amino-acids present in supplemented Williams' medium[4,7].

We have not had available a sample of adenosine triphosphate (ATP) and therefore have not been able directly to confirm Loofbourow's results[1]. However, in preliminary experiments which we are extending, we have applied a modification of Lohmann's fractionation procedure[8] to our wound hormone preparations. Assayed in unsupplemented Reader's medium the ATP fraction showed definite growth activity, as did the arginine phosphate and residual fractions. They all showed less activity than the parent extract, as would be expected from the previous findings and the assay conditions. Owing to the ease of hydrolysis of adenosine triphosphate it seems likely that our wound hormone extract would contain relatively small quantities of it as such. From the experiments it seems evident that fragments of the ATP molecule are active, and it may be that the phosphorylated adenosines (and guanosines ?) occupy a unique place n the control of growth, as suggested recently by Potter[9].

Recently, Leonian and Lilly[10] have stated that the yeast growth activity commonly attributed to unknown factors in yeast and tissue extracts is non-existent and may be duplicated by adding greatly ncreased quantities of certain members of the vitamin B complex (notably inositol, biotin and pantothenic acid) to the medium. In partial confirmation of this we find that tripling the quantities of these vitamins in our medium (that is, using per ml. nositol, 300 mgm.; calcium pantothenate, 360 γ; and biotin, 1·2 γ) raises our 24-hr. yeast crop from 1·05 mgm. to 1·6 mgm. in a typical experiment. However, further addition of the wound hormone preparation in quantities of 0·14 mgm. per ml., 0·2 mgm. per ml., and 0·56 mgm. per ml., gave respectively crops of 2·04 mgm., 2·28 mgm., and 2·46 mgm. Discussion with Dr. Lilly suggests that the difference between his finding and ours lies in the yeast growth period. In the 72-hr. period used by Leonian and Lilly the vitamins appear to obliterate the effect of other substances in the wound hormone and other extracts. This is not evident in the 24-hr. period used by Loofbourow and by us. It would thus appear that the additional proliferants (presumably nucleotides and nucleosides) in our preparations affect primarily the rate of yeast proliferation rather than the ultimate crop. This is also indicated by data of Loofbourow[1]. Experiments will be carried out to confirm this.

In summary, the nucleosides adenosine and guanosine, alone or combined with each other or with yeast adenylic acid, exert growth effects on yeast. Such substances, together with known growth factors, would seem to be present in wound hormone preparations from ultra-violet injured yeast cells. These substances exert a slight direct metabolic effect on yeast as observed manometrically. It is probable that these substances exert their effect on rate of yeast proliferation rather than on ultimate crop.

We wish to thank Sr. Mary of Lourdes McDevitt, I.H.M., for technical assistance, and Dr. C. N. Frey of the Fleischmann Laboratories for gifts of adenosine, guanosine and adenylic acid. The other sample of adenylic acid was purchased from Hofmann–La Roche as "adenosine phosphoric acid".

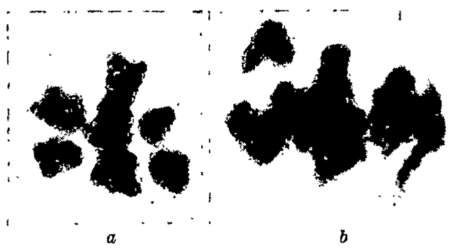
Chemical Nature of Chromosomes

THE staining properties of chromosomes have hitherto been regarded as due to their content of nucleic acid. Recently, however, Stedman and Stedman[1] have demonstrated the presence in animal chromosomes of a new protein, chromosomin, which they have shown not only to be the principal component of the chromosomes but also responsible for their staining properties. Part of their proof depended on the demonstration of the fact that when chromosomin, isolated from animal nuclei, is introduced into the dye solution formed by the interaction of hydrolysed deoxyribose nucleic acid and Feulgen's reagent (a solution which I propose to term 'developed nucleal stain'), it takes up the dye in exactly the same way as do the chromosomes. It is clear that if the Stedmans' interpretation of the mechanism of the normal Feulgen technique is correct, it should be possible to stain chromosomes directly with the developed nucleal stain. That this is the case is shown by the results, illustrated in the accompanying photomicrographs, which I have obtained with this stain on plant cells. This result provides confirmatory evidence of those of the Stedmans.



FIRST METAPHASE, (*a*) POLAR, (*b*) LATERAL VIEW, IN POLLEN MOTHER-CELLS OF CERTAIN SPECIES OF ALLIUM (FIXED IN ACETIC-ALCOHOL) STAINED WITH DEVELOPED NUCLEAL STAIN. × *c*. 1800.

The new process has certain advantages over other nuclear stains. A simple technique has been developed for its use, the details of which will be published elsewhere.

My thanks are due to Dr. E. Stedman for placing at my disposal the new stain and for his friendly co-operation.

A New Rapid Method for Penicillin Assay

VARIOUS methods of testing penicillin are in use in different laboratories, and while the accuracy of some of them is quite high, they all suffer from the disadvantage that some 12–18 hr. are required to obtain a result of any accuracy. Such a time-lag is a serious disadvantage in studying the production of penicillin—as the rapid change of *p*H which occurs under certain conditions makes it essential that harvesting should be carried out with the least delay if serious loss of activity is to be avoided.

The test outlined below, which has been in use for some time in these laboratories, has, in addition to its speed, other advantages. It is economical in space and materials, sterile technique is unnecessary and its accuracy appears to be as great as any other test. The test is based upon the inhibition by penicillin of the growth of a suitable group A β-hæmolytic Streptococcus—a 5 per cent suspension of washed sheep cells being used as an indicator. The penicillin to be tested is diluted to about 1 unit per ml. From this dilution quantities 0·20–0·10 are measured in 10 per cent steps, by means of a micrometer syringe, into 8 cm. × 1 cm. tubes containing 1 ml. of nutrient broth. To each tube is then added 0·2 ml. of a suspension of 500–700 × 10^6 organisms per ml. and 0·8 ml. of sheep cells. The tubes are then mixed by invertion and incubated in a water bath at 37° C. for approximately 3–3½ hr. They are then centrifuged and read for hæmolysis. A suitable standard and controls are included with each rack of tests.

The most critical factor in this test is the maintenance of the culture in a suitable state so that the suspension of organism does not contain any preformed hæmolysin. This is achieved by growing the culture on plain agar—and washing off with broth immediately before use.

Colour of Red Blood Corpuscles

IN a recent communication[1], Dr. J. R. Baker has asked why a single red blood corpuscle looks yellow instead of pink. Whether a thinned-out red colour is pink or yellow depends on the extent of its absorption in the blue end of the spectrum. Let us for simplicity regard white light as composed of equal parts of red, green and blue. Imagine two coloured substances with extinction coefficients as follows:

	Extinction	coefficients	
	Red	Green	Blue
Substance 1	0·3	0·7	0·7
Substance 2	[illegible]	0·7	7·0

At a certain thickness substance 1 transmits 5 per cent red, 0·1 per cent green and 0·1 per cent blue, while substance 2 transmits 5 per cent red, 0·1 per cent green and 0·00 per cent blue. At such thicknesses and above both substances transmit so little green and blue as to be red in colour. At a thickness about one fifteenth of this the proportions transmitted are—substance 1: 74 per cent red, 67 per cent green and 67 per cent blue; substance 2: 74 per cent red, 67 per cent green and 0·1 per cent blue. The colour of the first substance is 201 parts white (equal parts red, green, blue) and 7 parts red, that is, pink, while that of the second is composed of red and green which additively combine to give the sensation of yellow. If a different light source having a different red : green : blue ratio is used the tints will naturally be modified. The yellow colour of red blood corpuscles seen singly merely indicates the presence of a substance of high extinction coefficient in the blue region of the spectrum. The identification of a coloured substance is more satisfactorily made on the basis of its *absorbing* rather than on its *transmitting* qualities.

E. J. BOWEN.

Physical Chemistry Laboratory,
South Parks Road,
Oxford.
Sept. 18.

THE fact to which Dr. Baker directs attention can be readily understood if the absorption spectrum of hæmoglobin be considered in its entirety. In all the text-books attention is concentrated on the characteristic absorption bands in the yellow and yellowish-green, and the lower end of the spectrum is neglected. The very strong absorption in the violet, which helps to determine the colour of hæmoglobin at all concentrations, has therefore escaped the notice of many men of science.

A strong solution of oxyhæmoglobin absorbs completely all rays below the orange-yellow (585 mμ) and transmits nearly completely all those above it. The boundary (which corresponds to the upper margin of the α absorption band) is very sharp. The colour of such a solution is intense scarlet; on progressive dilution it changes through vermilion to a somewhat dull orange, and eventually to the pale straw-yellow of a single corpuscle under the microscope. The changes in the absorption spectrum that accompany these changes of colour are as follows. First a dim zone of transmission appears in the green, at about 505 mμ; its upper limit (the lower margin of the β band) is fairly sharp, but on further dilution its lower limit advances steadily through the blue-green and turquoise. Simultaneously with this extension a transmission zone in the yellow-green (560 mμ) appears, separating the α from the β band. The bands then become thinner and fainter, but at this stage absorption below the mid-blue (470 mμ) is still almost complete; and even at very high dilutions, when the β band is invisible and the α band very faint, absorption in the violet, below 425 mμ, is quite conspicuous.

Roughly speaking, therefore, one may say that a dilute solution transmits all but the violet and ultramarine; a solution of medium strength transmits the red, orange and much of the green and blue-green; and a strong solution only the red and orange. It is easy to understand that these will appear respectively pale yellow, moderate orange and intense scarlet.

Reduced hæmoglobin shows, as is well known, a single absorption band in the yellow-green, instead of the two of oxyhæmoglobin. This has scarcely any effect on its colour; its cherry-red hue at moderate dilutions, instead of the orange-vermilion of oxyhæmoglobin, is due to its much less vigorous absorption of the blue rays. But absorption in the violet is extremely strong, so that very dilute solutions have the same pale yellow colour as those of oxyhæmoglobin.

If, instead of diluting the solution, the depth of it through which the light passes is decreased, the results are exactly the same. It may be true of some dyes, as Dr. Baker says, that change of colour on dilution arises from molecular dissociation; but in most cases the explanation is analogous to that just given for hæmoglobin. This phenomenon of dichroism is much more widespread than is generally supposed. The most striking cases, such as chlorophyll and chlorocruorin, are well known; but the changes in hue on diluting methylene blue or copper sulphate (shift towards green) or erythrosin (shift towards orange) differ only in degree. Safranin, gentian violet, Bismarck brown and malachite green, which are respectively scarlet, violet, orange-brown and blue-green at moderate dilutions, are all deep ruby-red in concentrated solution.

The importance of dichroism in interpreting the results of colour tests on a microscopic scale is, as

---

[1] NATURE, 152, 331 (1943).

Dr. Baker suggests, very great. Such tests should always be performed first on a macroscopic scale, with the concentration of one of the reagents low enough for the colour generated to be only just perceptible. If the coloured substance formed is dichroic there will be a change in hue as well as a decrease in intensity of colour, and a similar change may be expected on a microscopic scale.

High-Angle Edge Flaking of Flint

THE communication by Mr. J. Reid Moir on this subject in NATURE of July 17 raises some interesting points.

The flint knappers of Brandon for more than a century past have severed their gun-flints from the parent flake at an obtuse angle platform-scar varying from 120° to 150°. Their blows, however, were delivered with an iron hammer on a flake held down on an iron anvil. The use of a punch enables a regular series of short scars to be formed at an angle of about 120°, as may be seen from the lateral edges of Danish axes. My own experiences in removing flakes by direct percussion forming platform-scar angles up to 140° were published in 1938[1].

Mr. Moir rightly states that the detachment of such flakes requires a heavy blow on a large nodule of flint. Palæolithic man apparently rarely used such blows, and usually only on the butt end of thick implements. Out of 1,800 measurements of platform-scar angles made in eighteen different human industries, only twenty scars were found with angles of 110° or more, or 1·1 per cent of the total. At the same time the percentage of angles of 90° and more varied from 0 to 18 per cent in the different industries, all the remaining angles being acute.

In flaked flints from Eocene deposits the percentage of high-angle flake-scars of 90° and more varies from 54 to 62 per cent. The age of these deposits rules out percussion by human agency.

In flaked flints of later Tertiary age from Puy Courny, the Kent Plateau, and below the Crag of Norfolk and Suffolk, the percentage of high-angle flake-scars of 90° and more varies from 62 to 70 per cent.

The high proportion of high-angle scars in the Tertiary flints contrasts sharply with the paucity of high angles in the human industries, and suggests that the Tertiary flaking was due to soil movement under pressure arising from solifluxion, foundering, or ice action. Laboratory experiments confirm the facility with which high-angle flake scars can be produced by rotating a flint edge under pressure against a hard surface.

Identification of Male Schistosomes in Uncommon Sites

IN view of the difficulty of identifying adult schistosomes except by the shape of their *ova*, the presence of adult males in a site where only one species is known to occur strongly supports the opinion that the worms may belong to that species, even though easily identified adults belonging to another species are present in the same host.

Two adult male schistosomes were found[1] in a puppy's eyelid after it had been treated with cercariæ, some of which developed into typical adult examples of *Schistosomum hæmatobium* in the liver. These had probably migrated from the liver as the adults of *Schistosomum spindale* are wont to do before accumulating in the nasal veins.

Although nasal schistosomiasis has not been reported in South Africa, ova typical of *Schistosomum spindale* are found either entirely alone or in combination with *Schistosomum hæmatobium* ova in the human subject and the larvæ have been recorded in pond-snails[2], but variation in the number of testes in the adult males renders their identification difficult.

The Welsbach Mantle

A THIN platinum wire immersed in flame gases acquires a temperature far greater than that corresponding to the mean molecular translational energy of the gases. The explanation appears to be that an abnormal dissociation exists in flame gases and that the products of the abnormal dissociation combine upon its surface[1,2]. This perhaps throws light upon the problem of the luminosity of the Welsbach mantle. A mixture of ceria and thoria in the Welsbach mixture proportions is an effective catalyst in the combination of hydrogen and oxygen[3], and it seems probable that when a mantle is immersed in flame gases high temperatures are reached at the active centres on its surface.

There is little or no abnormal dissociation in flame gases resulting from the combustion of over-rich inflammable mixtures[1,2], and it is of interest to note that the Welsbach mantle loses its selective radiating properties when placed in the reducing part of the flame[3]. The experiments of Nichols with niobium oxide show similar results[3].

Bulb Correction in Capillary Tube Viscometry

IN a recent letter[1] Mr. A. C. Merrington points out that, when a material for which the viscosity decreases greatly with increase in rate of shear is investigated in a capillary viscometer, the resistance offered by the bulbs is a greater fraction of that offered by the capillary than when a true fluid is tested in the same apparatus. He thinks it possible that in some cases where anomalies have been reported in the relationship of flow-rate to capillary radius, the results can be completely accounted for by neglect of the bulb correction. He also thinks that in other instances it has influenced the results without being the whole cause of the observed anomalies.

The need for determining or eliminating bulb correction in accurate capillary tube viscometry is obvious. In the paper in which the radius anomaly known as the 'sigma' phenomenon was first described[2], we wrote:

"For this more accurate work with larger bulbs it becomes necessary to correct the pressures for the resistance offered by the bulbs themselves. For this purpose the bulbs are connected directly with one another, and the pressures corresponding to a series of volume-flows are measured. By graphical intrapolation the correction, P_b, corresponding to each volume-flow can be estimated. As no appreciable increase in resistance is caused by introducing a few millimetres of narrow tubing between the bulbs, it may safely be concluded that no kinetic energy correction is necessary with these measurements".

We should be surprised to find that neglect of bulb correction has been a serious cause of error in subsequent studies of the relationship of flow-rate to capillary radius, and we regard Mr. Merrington's suggestion as rather misleading.

University of London External Examinations and the Technical Colleges

WITH reference to E. B. Moullin's communication in NATURE of August 14, I should like to deal particularly with his statement that "All external examinations are abomination and an evil rot in an educational system". He cites as his chief authority for this point of view Prof. A. N. Whitehead. Prof. Whitehead was chairman of the Academic Council of the University of London in 1924 when I was chairman of the External Council, and he co-operated enthusiastically with me in creating a new department in external work. A sub-committee of the Academic and External Councils in July of that year brought before the Senate (March 27, 1924) a proposal for assistance to external students, which developed into what has become known as the "Advisory Service for External Students". Prof. Whitehead gave most generous help in the furtherance of this proposition, and it was his ardent advocacy that persuaded teachers (represented by the Academic Council) to give most disinterested and sustained support to the scheme, which was adopted by the Senate with only two dissentients. Prof. Whitehead continued to take the liveliest interest in the progress of the Service right up to the time of his resignation from the Senate to fill his new office at Harvard.

The Advisory Service has been in operation for nearly twenty years. Some of the most distinguished teachers in the University constitute a panel of advisers, and have given invaluable aid in preparing courses of study, furnishing guidance on authorities to be consulted, etc. The Advisory Service thus carried out by the closest co-operation between the two sides of the University of London received the special commendation of the Statutory Commission dealing with the reconstruction of the University in accordance with the University of London Act, 1926.

The part played by the external examinations of the University in raising the standard of teaching and achievement in university and technical colleges throughout Great Britain has been widely acknowledged by the colleges concerned, and in no faculty more wholeheartedly than in the faculty of engineering, to which the majority of technical colleges must be assigned. The encouragement thus given by the opportunity of sitting for external degree examinations in engineering has resulted in a steady multiplication of colleges throughout the country (now more than fifty in number), which have raised their standard of teaching to a level that allows of their recognition as institutions submitting candidates for London degrees.

If I understand Mr. Moullin's argument correctly, it is that every technical college should be sufficiently self-satisfied to disregard any outside valuation of its adequacy. Such an attitude does not show the humility which is surely one of the most authentic attributes of the truly scientific mind, and it is not endorsed by some of the most important university colleges in the provinces. Indeed, there is abundant evidence from many such institutions that the standard of their work has benefited by receiving the confirmatory hall-mark of unimpeachable authority afforded by the performance of their students in London external examinations.

In this connexion I may mention a tribute paid to the external side of the University of London by the late Frank Granger, vice-principal of Nottingham University College. He pointed out in a letter that lies before me that his own distinguished career had been rendered possible by the opportunity of taking an external degree at London, and he referred to the advantage enjoyed by his College which for more than fifty-four years had prepared students for London external degrees, and he mentioned that in the year 1935 in which he wrote, the fees paid by his students to the external side totalled more than £2,000, an authentic index to the volume of entries. He went on to say that other university colleges than his own were equally appreciative of the service rendered by London in this respect.

The service to higher education which the external side of the University of London fulfils may perhaps be gauged by certain figures.

In the latest list, given by the University Grants Committee, of students at Oxford, Cambridge and London, the following figures are furnished for 1941–42:

Oxford	2,723
Cambridge	3,245
London (registered external students) ..	10,799
" " internal " ..	9,162

The importance of the function discharged by the external system of examinations in fostering educational relations with our Dominions and Colonies was handsomely acknowledged by the President of the Board of Education (Lord Eustace Percy) in a memorable passage of his speech in the House of Commons on the Second Reading of the University of London Bill (Hansard, Nov. 19/26, col. 2122) with which I shall close this letter. Lord Eustace Percy said:

"It has been one of the great glories of the external side that it has been a pioneer in the effort to make London in a very real sense an Imperial University, and that is the position which London must increasingly occupy. The demand for university education in this country from all our Dominions is growing every year; Oxford and Cambridge clearly cannot satisfy it. The University of London is clearly marked out as the University that can satisfy it."

E. Graham-Little.
(Chairman of the External Council,
London University.)

Importation of Technical Literature into Great Britain

About eight months ago, a copy of B. A. Soule's "Library Guide for the Chemist" was ordered for the Chemistry Library here, but so far the book has not arrived, presumably on account of its being an American publication. Everyone knows that in present circumstances, transmission of books from overseas must often be less rapid than in peace-time; could not some way be found, however, either to expedite transmission or to produce a limited edition of a useful work of this kind in Great Britain?

As most chemists are aware, almost all recent guides to the chemical literature are of American origin, and unfortunately few, if any, up-to-date British substitutes for these exist. Furthermore, on account of present conditions, many young chemists are being trained in a shorter time than is usual, and are being absorbed into industrial and other research laboratories without any previous research experience. This means that the training of these men in the full use of chemical literature can scarcely be adequately done at the university, and may, in extreme instances, be utterly neglected.

Since it becomes the responsibility of each man, after graduating, to continue to train himself in this technique—for without it he is defective as a research worker—it seems a matter of national importance that such aids as do exist should be made more readily available.

Science, Christianity and Truth

In Nature of July 17 Prof. Julian Huxley directs attention to the misunderstandings of the scientific point of view involved in two passages from Rev. Hardwick's review of Canon Baker's "Science, Christianity and Truth". Surely these misunderstandings are in some measure due to the scientific man's habitual reluctance to state his own *credo*? In common with any other philosophical attitude, the scientific one must take its stand on some primary assumptions, whether they be regarded as beliefs or as merely postulates. Science assumes an objective universe external to an observer and that there is some real relationship between the sense reactions of the observer and the universe. These assumptions are implicit in the criterion of "arriving at truth rather than error" by the "correspondence with fact" to which Prof. Huxley refers. They are implicit, too, in the conception of evolution and all that is based upon it; among other things, a belief in an evolutionary trend towards betterment of some sort and in man's power of fostering and furthering that trend. Many scientific men hold these ideas and hold them as articles of belief rather than as mere working hypotheses.

Granted this, they have good ground on which to reply to the assertion with regard to their position in relation to liberty which Rev. Hardwick quotes with approval from Canon Baker's book. For evolution implies variation and variation implies liberty.

C. Berkeley.

The Biological Station,
Nanaimo, B.C. Aug. 23.

James Prescott Joule and the Unit of Energy

Prof. Allen's inquiries (Nature, September 25, p. 354) confirm the conclusion reached by the late Prof. Lloyd James and reported in the *Radio Times* in February 1933. He found that twelve near relatives and friends of the man himself pronounced 'Joule' to rhyme with *cool*, six more distant relatives and friends rhymed it with *coal* and nine other friends rhymed it with *cowl*. On the other hand, among living bearers or friends of bearers of the name, the frequency was ten for *cool*, twenty-six for *coal* and thirteen for *cowl*.

Thus it may be assumed that in Joule's time in Manchester, the name rhymed with *cool*, but that the present tendency is towards *coal* (which, for the sake of those with a desire for precision, is, I suggest, an attempt to represent the pronunciation which phoneticians would write as dʒoul).

J. H. Awbery.

11 Carlisle Road,
Hampton, Middx.

If Prof. Allen can establish beyond doubt that Joule pronounced his name *jool*, not *jowl*, he will do lexicographers a valuable service. The pronunciation *jowl*, given in "Chambers's Technical Dictionary", was based on information obtained for our much older "Biographical Dictionary", so there is no question of its being a recent corruption. While giving the pronunciation *jowl* for the personal name in our "Technical Dictionary", we were careful to give the form *jool* for the unit, since inquiry among physicists showed that it is now universally pronounced so. Accordingly the "contradictory statements" appearing in Prof. Allen's extract from our definition are in reality a measure of our compilers' zeal. It is true that a literal error has crept into the definition, which we regret; but we stoutly disclaim the error of a century in Joule's birth date.

W. & R. Chambers Ltd.

11 Thistle Street,
Edinburgh, 1.

May I hope that the "jool" pronunciation of Joule's name will be adopted, if only in order to preserve the mnemonic:

"Old Dr. Joule he made this rule:
The self-same energee
Which lifts a gram of matter to
42640 c. [centimetres]
Will heat a gram of water through
One centigrade degree."

This is due to the late Dr. T. C. Porter, of Eton College, and presumably gives the pronunciation current about fifty years ago.

at Rothamsted Experimental Station,
Harpenden.

ASSOCIATION OF SPECIAL LIBRARIES AND INFORMATION BUREAUX

ANNUAL CONFERENCE

THE eighteenth annual conference of the Association of Special Libraries and Information Bureaux (ASLIB), following the precedent of the seventeenth conference last year, was held in the Royal Society's rooms at Burlington House on September 18 and 19. The attendance was considerably larger than in 1942, and at some sessions the accommodation generously provided by the Royal Society was barely adequate for the number present.

The report on the year's work presented to the annual general meeting on September 18, when Prof. R. S. Hutton was re-elected president, referred to a steady increase in membership to 390 as against 328 in 1942 and 297 in 1941. Although the Association's income has increased, the increase of expenditure due to such special activities as publications and the highly successful special library-training course initiated as a result of a suggestion at the 1942 Conference, has led to a small deficit, and the financial position of the Association was the subject of some keen discussion at the final session of the Conference on September 19, when Miss Ditmas, the general secretary, gave an informal paper on "Aslib : What it is Doing and What it Hopes to Do". The report also referred to the project for a Union Catalogue of Periodicals in British Libraries, the Index to Translations, and to the use made of the location indexes to current copies of European periodicals, as well as to the visit of the chairman of council, Mr. Edward Carter, to the United States at the invitation of the Rockefeller Foundation.

Following the annual meeting, the Conference opened with an address on "Information Services for the Scientist" by Mr. J. G. Crowther, of the British Council. Pointing out that the forces now being released by the application of science are such that scientific workers can no longer remain indifferent to the use made of their discoveries, Mr. Crowther urged that the social situation demands that the instruments of modern science should be handled with knowledge and judgment, not only by scientific men but also by the community as a whole. Accordingly the efficient organization and use of scientific information are among the chief problems of the day. Britain, he considered, can have no future as a first-class power unless she modernizes her scientific and technical resources ; and in addition to making existing libraries as convenient and efficient as possible, plans should be prepared for an adequate national system of scientific and technical information. This is a necessary part of the development of an adequate national system of scientific and industrial research. Referring to his experience in the supply of information overseas regarding British contributions to science, Mr. Crowther commented on the need for better information services, on difficulties in dealing with bibliographic inquiries in science, and particularly on the need for carefully classified lists of books, coupled up with an index containing critical reviews. The centralization of abstracting services is also desirable ; further, Mr. Crowther directed attention to the absence of any British Government medical library comparable with that of the Surgeon-General's Office at Washington. Medical literature, too, is in urgent need of rationalization, and after a reference to the proposals for an Institute of Scientific Information ventilated at the British Association Conference on "Science and the Citizen" earlier in the year, Mr. Crowther suggested that there are so many problems of first-class importance in connexion with the organization of science and the development of scientific and industrial research, from the national, the Commonwealth and the international point of view, that the appointment of a Cabinet Committee to study the matter and inspire the preparation of suitable plans is desirable.

The remaining sessions on September 18 were devoted to a symposium on the international rehabilitation of special library services. Mr. Theodore Besterman contributed to the first session, which was concerned primarily with the tasks and policy in library rehabilitation, a paper in which he proposed the establishment of an international library clearing house. The centralized collection and allocation of books in some such way would be a valuable contribution towards the systematic restocking of libraries, and Mr. Besterman referred particularly to the question of periodicals. Emphasizing the necessity of a plan which transcends national boundaries, Mr. Besterman stated that the ideas embodied in his paper are being considered by a United Nations Committee under the auspices of the British Council, with Prof. Ernest Barker as chairman. Prof. J. Timmermans followed with a paper on the restoration of the Belgian public libraries, and the ensuing discussion centred largely on the possibility of using the services of the National Central Library for the purpose in Great Britain, assisted by a proportionately larger Government grant, and on Mr. C. C. Barnard's proposals in a letter to the Press last July (NATURE, **152**, 106 ; July 24, 1943).

A paper by Mr. E. J. Carter was concerned with the technique of the problem, particularly that of special libraries and information bureaux. As a background to that technique he visualizes a fuller organization of academic life. In each country the primary division would be into national academies in which the user interests of science, history, the arts and education have their centres. These would be more than professional societies as we have them in Britain now : they would be the central organizing and initiating departments of the whole of each sphere of national life, and would be academies of working scientific men, etc. Each academy would have its documentation section responsible for seeing that its members are efficiently served in regard to the collection, processing and distribution aspect of such service. The national academies would be linked up with Continental councils, grouped so as to yield as large units as could be functionally efficient. Some such background, he considers, is essential in any scheme for improving the details of communication.

Mr. Carter then briefly reviewed some of the needs, such as the organization, first on a national scale and then an international scale, of the collection, processing and distribution of knowledge, of which Mr. Besterman's proposal was only one aspect. The essential point both in abstracting and in documentary reproduction is to co-ordinate and extend existing services rather than to create new. Finally, the operation of an efficient information service involves both the education of the personnel required for the services we have in mind and the education of our own special public. In regard to the former, the whole of the service must be adjusted to the special needs of the studies and operations to be served, while in regard to the latter an information service which derives its life from its users either as contributors or as recipients is not a bureaucratic processing machine but a positive and creative element in national life.

These discussions were echoed in that following Mr. F. C. Francis' paper on September 19 on "The British Museum as a Special Library". Pointing out that the librarian cannot be content with cataloguing and classifying his stocks but must always be on the look-out for means to make his books known and to make them play their full part in the growth of knowledge, Mr. Francis explained how, broadly speaking, the British Museum has itself tended to specialize on subjects that might be roughly grouped as humanistic. It is the practice of the Museum to attempt to add to its collections 'English' books printed abroad, and also to buy books by outstanding writers, and really important books likely to be of historical importance in every field of knowledge. Scientific works published in the general proceedings of learned societies and academies, or in series, or as dissertations will, almost certainly, be found in the British Museum Library in complete ranges, as will the publications of foreign Governments, which again include works in all branches of study. Generally speaking, the collections are strong on the historical side of most subjects and weakest in modern foreign technical literature in non-humanistic subjects. Even here, Mr. Francis pointed out that of 112 items on pp. 226, 227 of the "World List of Scientific Periodicals", the British Museum has seventeen, the Natural History Museum Library five and the Science Library twenty-two, while of the seventeen, five are not to be found elsewhere. Similarly, out of 87 items on pp. 510–11, ten are in the Museum (and three only there), five in the Natural History Museum, and sixteen in the Science Library. Again, the Museum has no fewer than 111 items not included in the recent ASLIB List of Scientific and Technical Periodicals received from the U.S.S.R. during the period 1933–42. Finally, commenting on Mr. C. C. Barnard's suggestion, Mr. Francis urged that we should first carefully consider the place which each library, whether a national library or a special library, can take in a properly thought-out scheme devised to fulfil the tasks allotted to it as economically as possible. The organization of collecting so as to provide up-to-date, accurate and complete information on the subjects covered requires a measure of unified control if special libraries are not to be doing the same work, and he thought centralization rather than dispersal of our great reference library services should be the ideal.

At the following session, Major Irving J. Newman described the organization of American Photographic Information Services in Great Britain and included a showing of the film "Report from the Aleutians". The afternoon session of the Conference on September 19 was devoted to a discussion on the co-ordination of abstracting, at which Prof. R. S. Hutton presided. Referring to the earlier ASLIB discussions and inquiry on this question initiated in 1931, and to Prof. J. C. Philip's paper "Efficiency with Economy in Abstracting", Prof. Hutton suggested that the discussion should centre on such points as whether existing abstracting services adequately cover the delegates' field of interest, and whether there is duplication in their particular fields. If they run their own abstracting service, is that because existing services do not cover the field, are too slow or cannot cater for their special needs? Again, can a centralized abstracting service adequately serve their special field of interests or secondary interests indirectly related to their main field of research? The discussion was opened by Dr. S. C. Bradford, who put the case for a central abstracting service with his usual ability. Mr. King gave a brief statement of the steps already taken in regard to collaboration in the preparation of scientific abstracts arising out of the report of the British Commonwealth Science Committee. Despite a full discussion, it cannot be said that any tangible result was achieved. Most of those who participated appeared to be of the opinion that whatever centralized abstracting service may be organized, specialized abstracts will still be required to supplement it.

SCIENTIFIC STUDY OF THE AMARYLLIDACEÆ

THE American Amaryllis Society is again to be congratulated upon the publication of its ninth year-book "Herbertia" for 1942 (From the Society, Orlando, Florida, U.S.A. 3.25 dollars post paid). The Society, through its able editor Dr. Hamilton P. Traub, has brought together a large number of short contributions which deal with all aspects of the Amaryllidaceæ. Detailed descriptions of the Ixolirion tribe, with keys and descriptions of species, are given by Dr. Traub, and include chromosome data for *I. tartaricum*. The genus Crinum is also the subject of a comprehensive review by Dr. J. C. Th. Uphof. Suitable illustrations play a considerable part in the correct recognition of species, and Major Albert Pam of Broxbourne, England, has prepared an extensive check-list of coloured plates of amaryllids which have been published in the literature. A new species of Hemerocallis, *H. altissima*, is described by Dr. A. B. Stout, who also outlines the various stages in the breeding of a red-flowered day-lily. Starting with *Hemerocallis flava*, *H. aurantiaca*, *H. Thunbergii* and the Europa day-lily, hybridization and selective breeding produced the Theron class, with petals almost wholly red. Further breeding has made possible the introduction of bi-coloured flowers, and blooms with various geometrical arrangements of red upon a yellow ground.

Cytology of the genus Narcissus forms the subject of a paper by Dr. Abilio Fernandes of Coimbra, Portugal, who is a recipient of the Society's Herbert Medal. Chromosome numbers for fifty-seven species, varieties and forms, with information about the relative sizes of various pairs, are combined with more general considerations. Diploids, for example, do not grow on acid soils (pH 3·7–6·2), whilst hypotetraploids ($2n = 26$) can grow on soils of moderate acidity and on neutral and alkaline ones (pH 5·7–7·8). Cytological studies also reinforce the morphological subdivision of the genus into three groups. Some vitamins, hormones, pyrimidines and purines, with certain other substances, were found by Dr. F. T. Addicott to increase the percentage germination and tube-length of pollen grains of Milla sp. This fact should materially assist breeders to effect cross-pollination between varieties otherwise difficult of fertilization.

Virus diseases are also considered in the year-book. Earl Hornback lists the species of Narcissus in order of resistance to such maladies, placing *N. Tazetta* as most resistant, with double forms, Poetaz and Poeticus varieties as most susceptible. L. S. Hannibal finds, however, that not many other genera of the Amaryllidaceæ are affected by mosaic diseases. Several factors in the propagation of alstroemerids are of scientific interest. Alstroemeria seeds, for example, must have sun before they will germinate, whereas seeds of Bomarea must be protected from the sun, according to Harry L. Stinson. L. S. Hannibal shows, among other factors, that in the further treatment of seedlings, alstroemerias must not suffer any crowding of the roots, otherwise flowers will not be produced. Vegetative propagation of Hemerocallis by crown cuttings has been further studied by V. T. Stoutemyer, who finds that the cuttings grow much faster and make greater weight if they are given six hours extra light each day, than in conditions of ordinary illumination.

Other aspects of practical culture, of harvesting, storage, forcing and of garden combination are dealt with in the volume.

It is difficult to escape the conclusion that knowledge of the horticultural science, genetics and taxonomy of the Amaryllidaceæ has advanced more than that of any other group during the last decade. Perhaps it is because "Herbertia" gathers together all the items into a connected whole, but there is also the specialist stimulus provided by a Society bent upon the encyclopædic study of a relatively small field which is replete with garden beauty, world-wide in origin and distribution, and full of scientific interest.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Friday, October 22—Saturday, October 23

Town and Country Planning Association (at the Royal Empire Society, Northumberland Avenue, London, W.C.2).—Conference on "Country Towns in a National Planning Policy".*

Friday, October 22—Sunday, October 24

Institute of Industrial Administration (at the Waldorf Hotel, Aldwych, London, W.C.2).—Conference on "Management in Action".

Saturday, October 23

Sheffield Metallurgical Association, at 2.30 p.m.—Discussion on "The Education and Training of Metallurgists" (to be opened by Dr. Edwin Gregory).

Monday, October 25

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 5 p.m.—"Flying Boats over Africa" (Kodachrome Film by courtesy of B.O.A.C., Commentary by Mr. Ronald W. Waugh).

Institution of Electrical Engineers (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "How Far is International Standardization in the National Interest?" (to be opened by Colonel Sir A. Stanley Angwin).

Association of Austrian Engineers, Chemists and Scientific Workers in Great Britain (at the Austrian Centre Swiss Cottage, 69 Eton Avenue, Hampstead, London, N.W.3), at 7 p.m.—Mr. David Cushman Coyle: "The Tennessee Valley Authority—Democratic Planning of a Water System in U.S.A.".

Tuesday, October 26

British Society for International Bibliography (at the Science Museum, Exhibition Road, South Kensington, London, S.W.7), at 2.15 p.m.—Mr. H. Rottenburg: "The Universal Decimal Classification as the Keystone of the Publishing and Bookselling Business"; Dr. R. L. Sheppard: "The Bureau of Hygiene and Tropical Diseases".

Chadwick Public Lecture (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 2.30 p.m.—Miss Margery Fry: "Ill Health and Ill Doing".*

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. A. Spencer Paterson: "The Size of the Family of the Business, Professional and Titled Classes"

Thursday, October 28

Oil and Colour Chemists' Association (Manchester Section). (in the Engineers' Club, Albert Square, Manchester), at 2 p.m.—Dr. W. J. S. Naunton: "Molecules without Tears".

Linnean Society of London (joint meeting with the Zoological Society of London) (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 3 p.m.—General Meeting; at 3.15 p.m.—Dr. J. F. G. Wheeler: "On a Humpbacked Whale taken in Bermuda in 1942"; at 3.35 p.m.—Mr. Gilbert J. Arrow: "Polymorphism in Giant Beetles"; at 3.55 p.m.—Dr. V. J. Chapman: "1939 Cambrid University Expedition to Jamaica".

British Institution of Radio Engineers (London Sectio (at the Institution of Structural Engineers, 11 Upper Belgrave Stree London, S.W.1), at 6.30 p.m.—Mr. John Logie Baird: "Colour an Stereoscopic Television".

Association of Austrian Engineers, Chemists and Scientif Workers in Great Britain (joint meeting with the Royal Nethe lands Institution of Engineers) (at the Institution of Mechanic. Engineers, Storey's Gate, St. James's Park, London, S.W.1), 7 p.m.—Mr. P. Kaufmann: "District Heating".

Friday, October 29

North-East Coast Institution of Engineers and Shipbuilde (in the Lecture Theatre of the Mining Institute, Newcastle-upo Tyne), at 6 p.m.—Dr. G. A. Hankins: "Experimental Fluid Dynami Applied to Engineering Practice" (Andrew Laing Lecture).

Saturday, October 30

Royal Anthropological Institute (at the Royal Society, Bu ington House, Piccadilly, London, W.1).—Centenary Meeting.

At 11.15 a.m.—Sir John L. Myres: "A Century of Our Work".

At 3 p.m. (at 21 Bedford Square, London, W.C.1).—"The Futu of Anthropology". (Dr. G. M. Morant: Physical Anthropology Prof. V. G. Childe: Archæology; Mr. R. U. Sayce: Material Culture Dr. R. Firth: Social Anthropology).

APPOINTMENTS VACANT

Applications are invited for the following appointments on o before the dates mentioned:

Educational Psychologist—The Director of Education, Municipa Buildings, Castle Street, Aberdeen (October 30).

Teacher (male) of General Science and Mathematics t students in full-time Junior and part-time day courses in the Colleg of Technology—The Director of Education, Education Offices, Rothe ham (October 30).

Horticultural Officer to take charge of advisory and demonstration work on commercial holdings and matters arising from th Horticultural Cropping Orders—The Executive Officer, Hampshir War Agricultural Executive Committee, The Castle, Wincheste (October 30).

Waterworks Engineer and Manager—The Town Clerk, Tow Hall, Halifax (endorsed 'Waterworks Engineer and Manager' (November 1).

Assistant Lecturer in Zoology—The Registrar, Universit College, Nottingham (November 1).

Assistant Lecturer in Agricultural Bacteriology—Th Registrar, University, Leeds 2 (November 6).

Professor of Engineering—The Registrar, University Colleg Singleton Park, Swansea (November 20).

Senior Lecturer in Electrotechnology at leading Technica College, Chile—The British Council, 3 Hanover Street, London, W. (endorsed 'Chile').

Assistant Engineer for the Government of Northern Rhodesi Public Works Department—The Ministry of Labour and Nationa Service, Central (Technical and Scientific) Register, Alexandra House Kingsway, London, W.C.2 (quoting Reference No. E.697).

Waterworks Engineer for the Nigerian Government Publi Works Department—The Ministry of Labour and National Servic Central (Technical and Scientific) Register, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.771).

Executive Engineer for the Sierra Leone Government Publi Works Department—The Ministry of Labour and National Servic Central (Technical and Scientific) Register, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. E.774).

Master of Engineering, whose main work will be the teaching c Engineering and the organization of Junior Technical Classes fo boys of 14 to 16—The Headmaster, The Gateway School, Leicester.

Civilian Technical Officer for a Government Department nea London with (1) expert knowledge of direct and alternating curren generators, regulating gear and switchgear, rotary and static converters, internal combustion engines, primary and secondary batteries radio communication senders, receivers and station accessories, telephone and transmission apparatus, including hand sets, carrier telephony and voice frequency telegraph equipment, teleprinter and cable laying plant, or (2) ability to assess modern designs of above equipment for maintenance spares—The Ministry of Labour and Nationa Service, Appointments Department, Q.S. 24, Kingsway, London W.C.2 (quoting Reference No. Q.16848).

For Government Posts in India—Industrial Planning Office (General), (Reference No. C.1911A), with sound mechanical training and at least five years' subsequent supervisory experience in recognize mechanical workshop: Design Officer (Reference No. C.1912A) first-class Mechanical Engineer with up-to-date experience in Desig of Light Mechanical Engineering Work; Assistant Industria Planning Officer (Ammunition) (Reference No. C.1913A), wit first-class mechanical training and knowledge of Modern Methods o Production and specialized experience in Light Press Tool Work an Machinery Components for Air Bomb; Assistant Industria Planning Officer (Non-Ferrous) (Reference No. C.1914A), with a least five years' experience in Production of Non-ferrous Metals an Alloys, and be familiar with Wire Drawing, Sheet and Strip Rolling and Sand Casting and Electrodepositing; Assistant Industria Planning Officer (Tools) (Reference No. C.1915A), with good experience in Machine Shop Process Planning and Jig Design experienc —The Ministry of Labour and National Service, Central (Technica and Scientific) Register, Alexandra House, Kingsway, London, W.C. (quoting the appropriate Reference No.).

EDUCATIONAL RECONSTRUCTION (4)

ADULT EDUCATION

ONE section of the White Paper on Educational Reconstruction, even at this stage, has caused considerable disquiet. That is the portion dealing with adult education. While the White Paper tells us that "without provision for adult education, the national system must be incomplete", there are few indications to show that the Government has any ordered policy for adult education. One cannot avoid the feeling that the paragraphs on adult education have been inserted diplomatically in order to assuage potential critics. There is little doubt, however, that it has had the opposite effect, and the concerted powers of adult educationists are being mobilized to persuade the Government to reconsider its attitude. That they will need as much support as possible may be deduced from the significant fact that in his amplifying statement when the White Paper was presented to Parliament on July 29, the President of the Board of Education made no specific reference to adult education.

To-day, some 80 per cent of the population of Britain left, or are leaving, school at fourteen years of age. That can scarcely provide adequate equipment for the citizens of a democracy ; and even this contracted education has in many cases been badly interrupted by the War. Yet these boys and girls who have left school at fourteen will be the majority of the electorate during the next thirty years ; the twenty-two million people who are already adult will decide the success or failure of the post-war social order. The educational provisions made for them may be indirectly the dominant factor in building the new educational order for children and young people adumbrated in the other parts of the White Paper. Yet the total additional expenditure which the Board is prepared to make during the first eight and a half years after the end of the War on technical *and* adult education is less than two and a half million pounds. No indication is given how much of this will be available for adult education alone. "Although the development of technical and adult education is not included among the matters to be dealt with in the first four-year plan, some allowance has been made for preliminary expenditure in respect of technical education." This can scarcely be said to be in tune with the high-sounding phrases in the White Paper about the value of adult education.

It must be brought home to Parliament before the Education Bill is discussed in the coming months that to neglect the education of adults will constitute an omission difficult to correct at a later date and one which will have profound significance in establishing a settled peace. The White Paper states that "it is only when the pupil or student reaches maturer years that he will have served an apprenticeship in the affairs of life sufficient to enable him fully to fit himself for service to the community. It is thus within the wider sphere of adult education that an ultimate training in democratic citizenship must be sought". Democracy and education go hand-in-hand, and a belief in one implies a belief in the other. This truism has been so frequently stated that one is inclined to repeat it mechanically, and the pregnant meaning it contains passes unnoticed.

The case for the democratic faith has recently been skilfully presented by the Sub-Warden of Wadham College. The simplest description of democracy, Mr. Leonard says, tells us that it means government by the process of "counting heads instead of breaking them". A democratic outlook acknowledges that reason and not passion is the light which should illumine the pathways of human progress. It maintains that men, for all their faults and failings, are in fact sufficiently reasonable and sufficiently sociable to make it possible for great States to be ruled by those peaceful and reasonable means which we call parliamentary government. The subjects of a State form one people and should share in its government; no minority must be outlawed or outraged; minorities can accept the decisions of a majority because the majority will treat them with consideration and not drive them into disloyalty.

If we accept this as a reasonable description of democracy, we can see that there is an inviolate connexion between democracy and education, and particularly adult education. Using the methods of argument and reason, and requiring a consideration of minorities such as men will show only if they can understand and appreciate points of view which are opposed to their own, democracy needs an educated people, and cannot develop to maturity until a truly educated outlook is more general than it has ever been in human history. (It is not inappropriate here to recall that the cleavage between democratic and totalitarian States broke up the international relationships of scientific men long before most people believed that it must inevitably end in war.) While it is true that real adult education can only thrive in democratic soil, one must realize, too, to change the metaphor, that the sounding-board of a democracy is the quality of its adult education.

All modern States, whatever their form of government, must strive to maintain and improve the level of scientific and technical knowledge. Only in a democracy will there be a concern for the free development of cultural standards through ample provision for adult education. With trepidation one considers the prospects for democracy in Great Britain during the next 20–30 years if no more attention is paid to adult education than is indicated in the White Paper.

Adult education should aim at building up the resistances of people against the powerful influences of propaganda and advertising, and here training in scientific method would be invaluable. The ability to view facts objectively, to form judgments without reference to what one desires (or fears) to find, or to any kind of personal valuation, has taken centuries of mental discipline to achieve and has become one of the basic factors in Western civilization. It is a method which needs more and more adherents, and these are only likely to be found if increased attention is paid to the education of students mature years.

It has already been pointed out that adult educat has striven almost alone to remedy for hundred thousands the deficiencies of an educational sys which ended for them on their fourteenth birthd Adult education has also had tremendous influe in creating a public will calling for wider and wi educational facilities for the new generation. It also left its imprint on the universities, and ind rescued some of their members from the danger unreality of academic aloofness. Further, thro adult education, the teacher has been saved from exclusive role of instructor, which must inevita leave a mark on his own character, and has of been placed in the position of a leader of discuss in which direct interchange of views occurs.

What can be done to cater for those who h already left school or will leave school during 20–25 years before the other proposals in the W Paper begin to take effect? Does the Governm fully understand how much life in the Serv has contributed to adult education, and what fe soil awaits the implanting of its seeds? Have t realized that Service life itself is a powerful addi to one's knowledge of the art of living, and that communal life of a barrack-room or mess is a sh educational corrective to one's own experience the place of individuals in society.

Everyone in the Services is familiar with numberless 'courses', and few people will not b been sent away at short notice to be given a pe of instruction at a centre where living in commu is the usual and accepted method. In the Royal Force these courses have often meant reside abroad, while both the Royal Air Force and Royal Navy are to-day sending men to the uni sities for six-month courses, during which time t live and study as ordinary undergraduates. I worth noting that about half these airmen sailors are taking courses in humane subjects—hist economics, philosophy, etc.—which can serve immediate utilitarian or vocational ends. Thous of men and women have passed through Mini of Labour training centres and many thousa have taken part in residential courses for yo leadership, some of them lasting so long as thirt weeks.

Besides all this there are the educational sche of the Services, which have become the grea development in adult education we have yet se Much of this work is carried on within the un but a great deal of it takes place during periods w Service men and women go into residence at universities for periods varying between a few d and three weeks. The majority of these courses h been framed to make the students more aware their responsibilities as citizens. Can we afford let this highly important field of work remain un tivated at the close of hostilities? What can be d in war should not be impossible in peace.

For all people, life is only beginning at eight

---

*Nature, 151, 438 (1943).

nd for most of them it is after this age that interest wakens in the deeper issues of politics, morals, science, religion and so on. The Scandinavian countries have recognized this and have provided ome two hundred adult education colleges for their sixteen million inhabitants. In Great Britain, to which the oppressed and subjugated peoples of the Continent nd elsewhere will look for a strong and inspiring ead in the post-war world, there are nine residential olleges, of which seven are grant-aided. The total number of students in residence in these grant-aided colleges is about three hundred.

The case for residential education has been well put in recent publications of the Educational Settlements Association and is admitted to be desirable in the White Paper. The value of uninterrupted study in congenial and agreeable surroundings, undisturbed by vocational, domestic or other preoccupations, will be evident to all who have had to rapple with the limitations of evening classes. There is the additional stimulus of sharing the pursuit of knowledge for cultural ends in community with other students of like mind and interests; the merits cannot be stressed too highly. It presents a training in democratic living which would be difficult to get by any other means, while the recuperative and recreative effect of a period of withdrawal from the stress and strain of everyday life and employment is too well known to need amplification. This uggestion has received considerable backing from the Trades Union Congress. "The most serious onsideration ought to be given to the possibility of nstituting in this country a system of short-term residential study for adults. The Government should ive a lead to employers to release workers for this ind of short course, with an assurance of reinstatement on their return." Residential colleges of diverse types that are already in existence in Great Britain ave demonstrated the potentialities of full-time study in residence and indicated the latent demand. If the Government intends the reference to residential colleges in the White Paper to stand for omething more than a political sop to their protagonists, it will have to provide for the purpose omething more concrete than the financial proposals et out therein.

In addition to residential colleges for full-time education, there will be needed many non-residential nstitutions for part-time or leisure study. This is dvocated in the White Paper. "There will need to be developed appropriate centres, which will not only provide the educational courses which the adult population may need, but will add to them the values associated with the life of a corporate institution". These should offer a suitable environment for the individual and social development of adults. The smaller citizen centres, of which Sir Richard Livingstone has been a leading advocate, would be admirable or the purpose until the larger all-embracing community centres could be provided. Citizen centres would be modelled on the lines of the educational settlements, of which there are nearly thirty in Great Britain at present. These provide a building which serves as a common hearth and home for all grades of students and other people engaged in social and educational activities in the neighbourhood. The citizen centre has much to offer to the development of adult education, and its place in the national system of education is one that needs earnest consideration.

For whom should adult education cater ? There are those who say that we should not in any way pander to people who can only be attracted by the superficial and meretricious, and that we should cater only for students of good intention*. Yet with all the powerful resources at their disposal, the voluntary organizations connected with adult education before the War could do no better than enlist 3 per cent of the possible field of recruitment. It is unfortunate that their admittedly wide experience has led some of the voluntary organizations to believe that they hold a vested interest in adult education and that theirs is the only adequate method of diffusing culture to adults. One is not unmindful of the great danger of promoting a semi-education which might become superficial and dilettante, but methods of 'popularization' will have to be extended if we are to draw a near maximum number of students into the world of more serious pursuits. It would be a pretence to suggest that the work carried out in air-raid shelters by the Workers' Educational Association has been of a very formal nature, and yet it has made a notable contribution to the methods of providing educational opportunities for adults.

The experience of the voluntary organizations has shown that the effective demand for the more serious 'tutorial' classes is limited. The problem to-day is to provide for a wider constituency without diverting the serious student from the type of class from which he will gain most benefit. Both types of students will be catered for only if the two main principles of adult education survive—voluntary attendance and free discussion. Above all, one must remember that the most important influences brought to bear on the adult citizen are not through education in the narrow sense, whether formal or informal. The part played by the Press, radio, the film, pamphlets and books is beyond measure.

In industry, besides the education which can be called technical and which is designed exclusively as a means of training people for earning their living, much is being done to raise the cultural level of the masses. Many big industrial organizations, for example, provide lunch-hour programmes which are an attractive feature of the winter's educational programme. These have often been the means of stimulating a more serious interest in subjects for which formerly the individual had little concern. The educational organizers in industry have excellent opportunities for promoting educational work with adults, and it is encouraging to note that their numbers are increasing.

From the foregoing it can be seen that the main problems of adult education have yet to be resolved, and a tremendous volume of research needs to be undertaken. In a democracy, the utmost variety of educational activities is essential. Ideally, there should be a different educational provision for every student, and it is not beyond the bounds of possibility that one day this will be achieved. Meantime, it is hoped that the proposals made by the Board of Education to encourage educational institutions for research will be used to a considerable extent in the wide and exciting field of adult education. The White Paper suggests that a maximum of £100,000 a year should be spent on educational research. Compared with the amount spent at present, this appears to be a reasonable sum. When viewed against the human problems that need urgent investigation, it seems as inadequate as the other measures proposed for adult education in an otherwise well-designed White Paper.

INDUSTRY AND SOCIETY (2)

RELATION TO GOVERNMENT

THAT there must be some measure of public control of industry is not now seriously disputed. It is accepted explicitly by Mr. Samuel Courtauld in his valuable paper "Government and Industry: their Future Relations", and also in the Unilever Paper on unemployment, which, however, points out that this does not necessarily imply direct control, since the Government already possesses powerful indirect means of control. Production must be adjusted to human needs, not human needs to production, as has too often happened when industry has lost sight of the essential purpose of economic activity. Fundamentally, it might be said that government intervention in industry should be no more than to ensure that economic aims are subordinate to wider social purposes, and to create the conditions in which the desire to make industry a form of essential social service can best develop. It is not a question of size but of direction and fitness for the purpose. The big business may, as Lord McGowan points out, be essential for some purposes; for others the small unit may best serve our end.

When we come to the methods by which that public control is to be effected we have already a wealth of experience on which to call. Of this Madge's book gives an admirably concise survey, if necessarily much less comprehensive than is given in the two chapters on British experience in the regulation of business in Cushman's "The Independent Regulatory Commissions". The question is whether with all this wealth of experience we can agree to think together, as Dr. Barker says, about a solution of economic problems which agrees with the logic and character of our democratic community.

The amount of common ground in the numerous statements and reports which have appeared on this question of government and industry give real reason for hope of a solution by the democratic process of discussion and compromise, provided the issues are clearly seen and the fundamental principles applied to test the soundness of each solution proposed for a particular problem or industry. Here once again Dr Barker is an invaluable guide. The issues of common life, he reminds us, do not exist in themselves or in things which can be done and then put away. They exist in persons, and are rooted and grounded in opinions and feelings. The reorganization of industry is really the reorganization of human beings, th redirection of their opinions and feelings. The action of government is fundamentally a psychological readjustment of the opinions and sentiments of human subjects, and no government can deal promptly and successfully with these real issue unless it knows at first hand the opinions and sentiments which constitute the core of those issues, and unless it periodically renews its knowledge to meet the constant renewal of these opinions and sentiments That is the fundamental justification of the democratic process, and the reason for believing with Dr Barker that the defects of business enterprise are due to the absence or imperfect development of th methods of open discussion and voluntary agreement which have been so highly developed in the State.

While there is no escape from the necessity o planning in the field of economics, planning enhance the importance of a democratic system of government. It is the essential corrective if human value and a sense of perspective are to be preserved, and in itself prevents planning going to the extreme limits seen in the totalitarian regime. Prof. Zweig in his book "The Planning of Free Societies", note that all planned economies have so far failed in practice to establish a real and successful self-government His appreciation of the work of the Tennessee Valley Authority and analysis of the causes of the failure o the American experiment in the self-government o industry under the New Deal are as pertinent i this connexion as his final review of the conditions for the proper working of planning.

Planning is not a franchise or immunity which lie outside the jurisdiction of free discussion and voluntary compromise. It requires efficient preparatio by research and investigation. Its objectives should be limited and clearly defined, for it is a powerfu implement which should be used with the greates care and foresight and applied only so far as is necessary; its abuse may easily destroy the most precious values. To employ the minimum measure of contro to achieve a given objective should be the supreme aim, and therefore planning should be restricted t general control.

As Dr. Barker points out, if the State itself forms economic organs such as an Economic Council or Council for Industry, it does so to facilitate the reconciliation and adjustment of claims and counterclaims prior to the action of the State, to promote the self-planning and self-discipline which are also integra to the economic system, and to achieve fuller and more informed discussion; and not to devolve upo them the burden of decision. When the leaders directors and experts in the various economic fields are encouraged to do the work of self-planning, tha work is not remitted to their unfettered discretion. The democratic State does not release economic self-planning and self-government from their necessary immersion in the general and total flood of political self-government. All economic planning must be compatible with the liberty of a general society of free minds, and statesmanship must ensure that short-term planning is restricted to its own proper issues and the long-term mode of planning, with its restraints on the distant future, reserved for the great issues which demand its operation.

These considerations suggest that the question of the relations of government and industry is really one of developing good tools of procedure and using them well. Fortunately we may read much encouragement in this respect in the Nuffield College Statement on "Industry and Education" and in Mr. Madge's survey, "Industry after the War". It is implicit in the distinction drawn between three main classes of industry and enterprise that we should choose the tools appropriate to the particular task. First, there are the key enterprises such as the basic utility and transport services. Secondly come major industries occupying vital positions in the nation's economy and apt to fall under monopolistic or semi-monopolistic control, and thirdly there are industries of smaller or medium size to which these conditions do not apply.

For the first there is general agreement that the appropriate form of control is a public corporation, combining a high degree of independence in operation with the necessary safeguarding of the public interest by remote public control. Such control may vary widely in type, and each key industry will require treatment appropriate to its special operational conditions. While the only extension proposed by the Nuffield College Statement for the public corporation is that of transport, it is made clear that the principle is capable of further application, and a timely warning is uttered against the danger, in establishing new forms of industrial organization, of treating as static a fluid situation. Every care must be taken to avoid impeding structural change due to the development of new techniques, or to give a group of producers any vested right to impede the growth of new processes either within the industry itself or outside.

For the second main group of industries the statement proposes the establishment of industrial boards. These would be statutory bodies presided over by chairmen appointed and paid by the State. These boards would be responsible, in consultation with the economic organs of the government, for the formulation of general economic policy for the industries concerned, interpreting the State's requirements to the industry, and the requirements of industry to the State. Consisting mainly of representatives of the industry, including those of labour, they are conceived as a measure of industrial self-government which will promote efficiency while safeguarding public interest, in particular against monopoly. They aim at throwing on industry the responsibility for conducting its own affairs under adequate safeguards for the public interest.

These proposals would go far to meet the dangers to which attention has been increasingly directed of late. They bear some resemblance to the tribunals proposed in 1919 by the Report on Trusts, when the public interest is adversely affected by monopolist organization. The statement is even more explicit on this point in a further section. It advocates dealing drastically with forms of profit-maintenance which result in the indefinite survival of inefficient producers, as well as in unduly high profits for the more efficient. The inefficient producer, unless he is made efficient, must go, subject only to the need for spreading the disappearance of uneconomic enterprise over a period long enough to avoid serious hardships or widespread unemployment.

There are other suggestions with regard to machinery of government in the Nuffield College statement which deserve note. The importance of substantial changes in the recruitment and organization of the public services and in the methods of industrial administration is stressed. Apart from the development of a technique of control and administration which will be effective and reasonably simple both from the point of view of the business man and of the Civil Service, it will in effect be necessary to develop a kind of public administration to deal with the State's new and expanding functions in the industrial field. This in turn involves recruiting new types of men and women, and once again we find emphasized the importance of closer assimilation between the rates of salary paid in public and in private business, of encouraging freedom of movement between publicly and privately administered concerns, of ensuring that technical as well as administrative ability is given the fullest recognition and scope, and of attention to the right training of those who are to enter the service of industry and commerce.

Further, public enterprises, urges the statement, should be so managed as to cover costs, including a reasonable return on their real capital assets, and where any element of subsidy is deemed necessary in the public interest, it should be open and not concealed. To avoid undue rigidity the managerial and technical staffs of public industrial enterprises should not be called upon to work under Civil Service conditions or be given similar guarantees of permanence, although the arrangement of pensions schemes so as to facilitate migration into and out of the public services is advocated. Similarly, the highest administrative positions in all branches of the public industrial services should be effectively opened to all possessing the right personal and technical qualifications, and should neither be the preserve of a particular administrative class nor closed in practice to the best men by inferior standards of remuneration and conditions of employment. Once again we encounter the suggestion of the constitution of standing parliamentary committees as a means of making parliamentary supervision of economic policy more practical and effective, a suggestion which merits more solid reasons for negation than the Government has yet given in Parliament. The publication of informative accounts is only one of the further measures which the statement suggests to encourage confidence in the integrity of industry and to overcome past prejudices.

The resemblance between this picture of the relations between government and industry and the practical target outlined by Mr. Madge is striking. Mr. Madge visualizes a Minister of Production, but with extended powers and functions more clearly defined, and assisted by both an executive staff, drawn largely from men with experience of the productive side of industry, and a research and advisory staff, to survey industrial problems and draft plans for their solution. Members of this section should not be permanent members of the Civil Service, but drawn from the ranks of management, the professions, the trade unions and the universities. Use would also be made of independent research work in the universities and elsewhere. A similar proposal has since been advanced in the report of the Sub-Committee of the Liberal Party.

Under this government machinery there would be three types of industrial organization, all of which would be given a fair chance to prove their worth : State-owned and State-managed ; privately owned with some or all directors appointed by the State ; and privately owned and privately managed. In some industries all three methods of control and management might be used experimentally ; in others a whole sector would be State-owned or privately-owned. Provision would be made in all types for joint consultation with labour on labour questions and other matters both at the works and at the national level, and books and records should be open for inspection by the research and advisory section of the Ministry of Production, which would review the efficiency of these methods and make its findings public. It will be noted that Lord McGowan recently advocated a step in this direction in recommending the registration of every international trade agreement with the Board of Trade, so that the Government would possess a complete picture of British participation in cartels.

What is hopeful in this whole approach is the emphasis laid on co-operation and a new spirit in industry. Machinery, either in the mechanical sense or in that of organization, is not enough. True it is that there are severe limits to the extent to which industrial democracy is practicable. The number of those sufficiently interested, apart from the question of technical qualification, to take any continuously active part in the management of an industry and the determination of working methods and conditions is relatively small. But while it is important to do everything possible to provide outlets for originality, energy and organizing ability, and to imbue all members of an industry from its directorate downwards with the spirit of public service, it is important that the humblest workers should feel that they have the opportunity to rise higher according to their ability, that their treatment is fair, and that their work provides worth-while opportunities for human energy and skill. If we succeed in this, it will matter little to the workers in any industry that general policy and technical control must be ordered from above. Secure that policy and control are ordered in the general interest of the community, they will recognize that power as legitimate power, and find in their occupation once more the social satisfaction which is the basis of a functioning society.

It should be noted that the Nuffield College Statement looks to social security legislation on the lines of the Beveridge Report as providing a necessary foundation for better industrial relations as well as to this greater publicity, and its concluding emphasis on the key factor of management and the powerful reaction of the situation on the position of managers and technical staff will be noted by scientific workers.

The fuller recognition of industrial management as a skilled profession, requiring both high personal qualities of enterprise and imagination and appropriate forms of special training, should not only improve the technical efficiency of industry but also foster good relations among all who are partners in the work of production. Moreover, the more industry becomes a partnership of all grades and sections of those engaged in it, the greater become the demands upon its managers for skill in the democratic handling of men as well as in the technical sphere. But even the question of closer collaboration between industry and education is secondary to that of collaboration between industry and the consuming public, and between those responsible for the direction and management of industry and those they employ. All engaged in industry must put first in their relation to industry the aim of serving the public, so that no question of sectionalism or exploitation can arise to disturb the confidence and good relations existing between industry and the rest of the community.

CHEMICAL PHYSICS: THE COMMON THEORETICAL BACKBONE OF CHEMISTRY AND PHYSICS

Introduction to Chemical Physics

By Prof. J. C. Slater. (International Series in Physics.) Pp. xiv+521. (New York and London : McGraw-Hill Book Co. Inc., 1939.) 33*s*.

A WORD of apology is due to this book and its author for the delay in this review. The review copy was received by the reviewer just before he started for Canada on a liaison mission which lasted some ten months. On his return the book was overlooked until recently, when, during a prolonged period of leave, it was found and studied with avidity, and the writing of this notice at last undertaken. The book is excellent, and, no matter how great the unfortunate delay, deserves a proper notice in the columns of NATURE.

What precisely is 'chemical physics' ? The author gives one answer in his preface which the reviewer willingly accepts. One may define, roughly, chemistry as the science of atoms and the way they combine, and physics as the science of interatomic forces and the large-scale properties of matter resulting from ose forces. One may even deplore, nowadays, at physics and chemistry were ever separated, ough one must admit that prior to the developments f the last forty years such separation seemed natural nd necessary. But the tendency both of theory and f experimental technique has been to emphasize e oneness of the science of the properties of matter, f which chemistry and physics are two most intimtely linked branches, with a very wide range of udy in common. To stress the importance of this mmon field in which both chemists and physicists ust be trained, it is useful, and indeed essential, have a name for it. An earlier attempt at a arriage of these two sciences gave rise to the name hysical chemistry' for the range of study then ntemplated as a common range. This name, therwise suitable, cannot therefore well be used to escribe the very wide common field of the united emistry and physics of to-day. Physical chemistry as flourished in the meantime and acquired a gnificance of its own as the study of a limited mmon ground of chemistry and physics, covering ch subjects as the applications of thermodynamics d kinetic theory to the properties of gases, liquids d (particularly) solutions—no attempt has been ade to be exhaustive. Since physical chemistry pre-empted, and for want of a better, the author oposes the name 'chemical physics' for the widest ssible range of studies common to both chemistry d physics that it is possible to contemplate day.

Defined in this way, chemical physics really covers l theory of and experiments for the properties of atter, for which the atomic or molecular structure matter is relevant, both in equilibrium and nonuilibrium states. Such a study could only be fully vered in many large volumes. What is attempted re is less ambitious and far more useful. It is to esent the elements of chemical physics in a way at demands the minimum of mathematical technique om the reader, and, as the reader will frequently a chemist, in a way that is intelligible without uch previous study of theoretical physics. Thermonamics, statistical mechanics and kinetic theory rm, of course, a vital part of the subject, and are ven in Part 1 of the book. They are the essential k between the properties of atoms and molecules ven by the quantum theory and the properties of atter in bulk. They are presented throughout in form that has been chosen for reasons of simplicity d freedom from mathematical difficulties rather an logical beauty, and on this score little exception n be taken to the author's choice. For the nonathematically minded physicist, and above all emist, it will give an entirely admirable training this fundamental part of chemical physics, and r the mathematically somewhat more ambitious equally admirable introduction. It provides a urse of study suitable for a Part 2 Tripos student physics or in chemistry with any aptitude at all r formal mathematical theory.

Having covered the vital "Thermodynamic" ound in Part 1, Dr. Slater proceeds in Part 2 to ply the theoretical techniques just introduced to e various states of matter and phase equilibria. is part proceeds on well-established lines and is n excellent elementary account of this part of the bject, the needs of the same type of student being rne in mind throughout. The most interesting vel features of this part of the book—novel, that for such an elementary treatise—are the careful elementary discussion of melting and of the entropy difference between a liquid and a crystalline phase of a simple substance in Chapter 16; a discussion of phase equilibrium in binary systems covering the liquidus and solidus curves of a binary metallic alloy and the complete phase diagram for the mixtures copper–magnesium and copper–zinc, designed to whet the appetite of the budding metallurgist, in Chapter 17; and phase changes of the second order with special reference to order-disorder transitions in copper–zinc systems in Chapter 18—the whole expounded with elegant simplicity.

In Part 3, Dr. Slater passes on to the other main branch of the subject, atoms, molecules and the structure of crystals, in which thermodynamics plays a minor part, as most of the structures concerned are predominantly ordered at all temperatures, and the fundamental theoretical technique is that of the quantum theory. Thermodynamics survives in this part mainly in the theories of radiation (Chapter 19), thermionic emission and the Volta effect (Chapter 28) and the electron structure of metals (Chapter 29), where of course the photons and electrons still need statistical handling to give the properties of bulk matter. Here again the students' need for simplicity is carefully watched; *a priori* knowledge of the quantum theory beyond the barest outline is not essential to the reader. Results of the quantum theory are quoted and used mainly in a descriptive form, which the student of chemistry should be fully capable of following without study of their theoretical basis, unless he is interested to do so and willing and able to acquire the necessary mathematical technique. The outstanding feature of this part is provided by the three chapters (24–26) on homopolar bonds in inorganic molecules, organic molecules and the silicates respectively. Nothing but the simplest descriptive accounts of the simplest cases is of course attempted, in terms of shared electrons. The reader is told clearly where difficulty arises, as in the benzene ring. Nothing much more is possible without a here unwarrantable dive into the quantum theory of resonance. The bare statement, however, that the quantum theory accounts perfectly satisfactorily for these apparent difficulties of the shared electron picture might perhaps be backed up by suitable references, making an exception for once, in view of its importance, to the author's no-reference policy. The book would be improved thereby. Nor is the printing too happy in these chapters. The double dot notation of G. N. Lewis for the pair of shared electrons is admittedly very difficult to lay out for the printer for any but the simplest molecules. The reviewer would like to see even more of the structural formulæ not laid out in type, but drawn and reproduced from small blocks set in the text—an expensive method but amply justified by the added clarity it would give in this important part of this valuable text-book.

Teachers and students alike of elementary chemical physics, the wide field of theory which is rapidly unifying chemistry and physics into a single science (or at least into two close-knit branches of a single science), owe Dr. Slater a profound debt of gratitude for this book. It was a book that badly needed writing. The temptations along the author's path to indulge in too advanced ramifications have been nobly resisted. Only those who have planned and failed to write an elementary book in this field will appreciate fully the devastating difficulty of this success.

R. H. Fowler.

HISTORICAL PLANT GEOGRAPHY

An Introduction to Historical Plant Geography

By E. V. Wulff. Authorized translation by Elizabeth Brissenden. (A New Series of Plant Science Books, Vol. 10.) Pp. xvi+224. (Waltham, Mass.: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1943.) 4.75 dollars.

THE study of the areal distribution of plant species, genera, and families is what is generally understood in Great Britain by 'plant geography' or 'phytogeography', as distinct from the wider field of 'plant ecology'. It is in this sense that Prof. Wulff employs the term in the title of his book which, however, is expanded to "Historical Plant Geography" (without altering what we should regard as the proper content of a phytogeographic text) in order to convey the emphasis required by the author's outlook: "Historical plant geography has as its aim the study of the distribution of species of plants now existing and, on the basis of their present and past areas, the elucidation of the origin and history of development of floras, which, in turn, gives us a key to an understanding of the earth's history".

No branch of science could, more than this, need the fullest and most unreserved international co-operation, and it is a welcome sign that it should have been possible during war-time to get the work of a distinguished Russian botanist translated into English, and that this work should have been published through the activities of an enlightened Dutch *émigré* organizing botanical publications in the United States. British workers have in the past contributed much to the foundations of this subject, as can be shown by the mere mention of the names of Lyell, Forbes, J. D. Hooker, Darwin, Wallace, Willis, Ridley and Guppy. Nevertheless, it cannot be denied that in recent years it has lost much of its attractiveness as a subject of research to British botanists, probably in part because of a rather nebulous character consequent on its lack of exactitude and experimental techniques in comparison with other aspects of botanical investigation.

The subject, all the same, has moved steadily forward, and a considerable bulk of work done by Continental, and especially by Russian, phytogeographers is in this book made available to English-speaking botanists, while a very concise foreword by Hugh M. Raup makes a most helpful survey of the very significant American literature which has appeared on the subject in the last few years. The present volume is the first of three by Prof. Wulff and comprises a general and theoretical treatment of the principles of plant geography; the second, already written, is a "History of the Floras of the World", and the third, in preparation, deals with the changes in floras caused by man's activities. We hope that in due time all three volumes will appear in English, but meanwhile the first of them is most opportune. This is particularly so since the last few years have furnished to the phytogeographer such valuable new tools and so much fresh evidence, that a phase of expansion of the subject clearly lies ahead. Of this our botanical students are vaguely or not at all aware, and this first English text to reveal the new potentialities must therefore be valuable and welcome.

We can best convey the content of the book by the chapter headings: (1) historical plant geography: scope, relation to allied sciences, methods of investigation; (2) history of the science; (3) areas, their centres and boundaries; (4) the origin of areas (5) types of areas; (6) parallelism in the geographica distribution of plants and animals and correlatio between the distribution of parasites and that o their host-plants; (7) artificial factors in the geographical distribution of plants; (8) natural factor in the geographical distribution of plants; (9) th migrations of species and floras and their causes (10) historical causes for the present structure o areas and the composition of floras; (11) concep of floral elements.

Though impartially surveying the subject as whole, Dr. Wulff emphasizes throughout his ow attitude, that the primary object of the study i the revelation of the history and of the mechanism by which present areal distributions were achieved He stresses that we must bring to this study ever scrap of relevant evidence of fossil plants—"th importance of such data should not be unde estimated, since they constitute the only direc evidence available for establishing the history of flora". This attitude also involves the recognitio of the results of pollen analysis and other studie bearing directly upon the history of vegetationa migration and equally upon palæoclimatology. D Wulff assigns very great importance to large climati changes in altering the geographical range of plant He insists also that "Biogeographical conclusion only find definite confirmation, when it is possible t base them on a geological foundation. . . ." Th search for such foundations leads the author to co sideration of the alternative hypotheses of submerge continents, sunken land-bridges, and continent drift, as bases for explanation of present and pa plant distribution. He considers that the phytoge graphic data decisively support the latter type explanation despite the present inadequacy of th Wegener hypothesis for the Pacific region. It interesting to find that so experienced a phytoge grapher considers the influence of man to have bee relatively unimportant, and he agrees with Will in stressing the inability of introduced species spread into undisturbed natural communities. Indee it is suggested that both cultivated plants and the associated weeds have lost many of the adapti mechanisms needful for such expansion. Slowne of natural distribution is also emphasized: "Plan are dispersed as a result of the transport of the seeds by natural means only slowly and graduall gaining new territory step by step". There is n strong preference for one school of thought as again another, a broad objective width of approach chara terizing the whole book, the author, for exampl accepting and explaining relic distribution are with the same clarity and fairness that he gives the patterns formed by the expanding groups whe new species are being created.

Dr. Wulff rejects no type of evidence bearing the history of floras: study of the characters of th distribution areas themselves, critical taxonomic an morphological investigations of the group concerne the modern cytogenetical evidence, ecological adjus ment of the species, the effectiveness of dispers mechanisms, the nature and distribution of pla parasites and hosts, all are laid under contributio as is indeed logical and inevitable. That the resul are not always clear and beyond question is due the sparsity of available data. Dr. Wulff has show from how wide a field such evidence must com and on how wide a front advance in this subject now recommencing.

H. GODWIN.

The Royal Institution

By Thomas Martin. (Science in Britain Series: Published for the British Council.) Pp. iv+46+4 lates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1942.) 1*s*. net.

BEHIND its imposing Georgian front, the Royal Institution in Albemarle Street, London, coneals well-equipped laboratories fitted up for research in the physical sciences, a comprehensive library of general as well as scientific interest and a lecture theatre with all the aids that modern science has provided for the use of the lecturer. It was founded y Count Rumford, that remarkable genius who combined politics with philanthropy and both with science. Rumford, who was born in Massachusetts, New England, of a family of English descent, had held the post of under-secretary in the Colonial Office in London, and later had taken office under the Elector of Bavaria, in whose service he returned to London in 1798. He decided to remain in London, nd in 1799, with Rumford as the prime mover, the Royal Institution was constituted, "for diffusing the nowledge and facilitating the general introduction of useful mechanical inventions and improvements, nd for teaching by courses of philosophical lectures and experiments the application of science to the common purposes of life".

Mr. Thomas Martin has been general secretary of the Royal Institution since 1929 and knows its history intimately. In the present booklet he outlines the inception of the Institution and skilfully sketches the many scientific developments with which it has been associated through its distinguished line of professors and directors, from Rumford himself, through Davy, Faraday, Tyndall, Dewar and Sir William Bragg. Mr. Martin has accomplished the difficult task of compressing a story full of interest into a brief but fascinating booklet.

Diseases of Vegetables

By Donald E. Green. Pp. vii+208. (London: Macmillan and Co., Ltd., 1943.) 8*s*. 6*d*. net.

IN the monthly issues of the *Journal of the Royal Horticultural Society*, January 1941–April 1942, there appeared a series of excellent papers by Mr. Green ntitled "Hygiene in the War-time Vegetable Garden". These have now been brought together, revised and expanded to form the present book, which gives in brief but adequate form for market gardeners and amateur growers of vegetables information concerning the recognition and treatment of diseases of their crops, illustrated by a very rogues' gallery of excellent portraits of diseased plants.

Only one who has had much first-hand experience of diseased plants could write with so much practical insight as this book possesses, and only one knowing his growers intimately could have sensed and met their needs so well. Especially will all growers welcome he admirable "Key to Disease Symptoms" with which the book opens and the clear recommendations of practical measures of control with which it ends. The author is described on the title page as "Mycologist to the Royal Horticultural Society", but his book includes, in addition to the fungal diseases of vegetables, those caused by bacteria, viruses, and the various non-parasitic agencies such as unfavourable conditions of soil or cultural treatment.

The text is written in a simple but, at times, repetitive and wordy style with occasional sentences, statements, or omissions which might with advantage be reconsidered when a second edition is called for. For its price the book is most agreeably produced, and it should serve the needs not only of professional market gardeners but also of the multitude of amateur war-time growers who are apt to feel distressed and very helpless when faced with unexpected and strange lapses in behaviour on the part of their allotment vegetables.

Statistical Tables

For Biological, Agricultural and Medical Research. By Prof. Ronald A. Fisher and Dr. Frank Yates. Second edition, revised and enlarged. Pp. viii+98. (London and Edinburgh: Oliver and Boyd, 1943.) 13*s*. 6*d*. net.

THESE tables, first issued in 1938, were early recognized as an authoritative production in the domain of statistics as applied to biology. The main modern tests of significance, many the work of the authors, are covered; the introduction is a mine of knowledge in itself, and the tables cover all the contingencies envisaged.

This edition, which maintains the standard of the first even to the quality of paper used—no small achievement these days—incorporates new features. Additional tables are provided for precise testing of the significance of the difference between sample means when it is not valid to pool the estimates of variance. One essentially practical problem can thus be dealt with, namely, the comparison of estimates of a physical constant, one based on numerous data of low precision, the other on a small quantity of precise observations. An extra table provides the limits of expectation for the probability of an event observed to occur a number of times in a series of trials, and thus supplies a more direct solution than hitherto of another practical problem. The densities of organisms estimated by the dilution method can be easily calculated from a new table.

The complex subject of balanced incomplete block arrangements, used in field trials, involves the tabulation of combinatorial solutions, which have been simplified by the more extensive use of solutions of the cyclic type. A new type of square arrangement is described in the introduction.

The value of the volume is enhanced by the worked examples illustrating the use of the tables.

J. WISHART.

Practical Physics

By Prof. Marsh W. White, Dr. Kenneth V. Manning, Prof. Robert L. Weber, Dr. R. Orin Cornett, and others on the Physics Extension Staff. (Pennsylvania State College Industrial Series.) (Prepared under the direction of the Division of Arts and Science Extension, the Pennsylvania State College.) Pp. x+365. (New York and London: McGraw-Hill Book Co., Inc., 1943.) 2.50 dollars.

THIS course of study, which is stated to have been tried out on a large scale in Pennsylvania during the War, resembles both in scope and quality some of those devised for evening classes in physics that are customary in Britain for engineers attending National Certificate courses. The emphasis is on mechanics, heat, and current electricity; less attention is given to sound and light. Each chapter reads like the record of a lecture, enlivened by popular illustrations and numerical examples, and followed by a simple experiment, performed either by the lecturer or by a group of students. Unlike several British books having similar titles, this is not a guide to precise experimental technique. The word "practical" in the title may perhaps be justified by saying that the lectures were designed to suit "practical men" in the sense of people of *I.Q.* about 120, who are familiar with tools, who have scant time for study, and who may be tired after a day's toil. Theory, such as occurs in first-year university courses, is here cut out as much as possible: there remains a little algebra and trigonometry, but no calculus. For example, a chapter on uniform circular motion begins with pictures of machines, states the formula for centripetal force without proof, and explains carefully its general interpretation and briefly its applications to aviation, to cream separators and to banked roadways. The chapter then offers a set of numerical examples, and ends with an experiment in which a girl student is shown holding a vertical glass tube through which passes a string, attached below to a weight, and above to a mass which she whirls in a horizontal circle. A blank form is provided for the observations and deductions.

Protest must be made against the reappearance (on p. 56) of the old fallacy that the time taken for a rise of temperature to move along a metal bar depends only on its conductance; whereas, in fact, its specific heat and density are just as essential.

Honours graduates in physics, who are about to begin to lecture in National Certificate courses, would find in this book a guide to what is possible in those circumstances. L. F. RICHARDSON.

Recent Advances in Galactic Dynamics

By Prof. A. C. Banerji. (Lucknow University Studies, No. 15.) Pp. vi+116. (Lucknow: Lucknow University, 1942.)

THE author of this book was invited to give three extension lectures at the University of Lucknow in 1940 on galactic dynamics, and they have now been published in the form of a monograph. The first lecture deals with polytropic configurations of rotating gaseous matter, and provides an excellent summary of the work of investigators from the earliest times up to the present. It ends with a brief discussion of the numerical solution of the differential equations which occur in the cases of polytropic configurations of rotating gases. The second lecture summarizes the investigations of Hubble, Jeans, Brown, Vogt and Lambrecht, Lindblad, and a number of Indian workers, including the author, on spiral nebulæ. A full account of the researches of Indian workers has appeared (*Phil. Mag.*, 7, 28, 118; 1939), and also in a number of Indian publications of more recent date. The origin of the solar system is considered in the third lecture, and the various theories to explain it are dealt with, from Swedenborg and Kant's nebular hypothesis to the recent theory of Lyttleton that the sun was a binary, its companion being disrupted by a passing star, the planets and satellites being formed from the debris. The investigations of Bhatnagar are considered and these have an important bearing on certain problems connected with planetary formation. He has shown that there is no possibility of the formation of the ribbon, from which the planets were supposed to be formed, by a close encounter or even a grazing collision between stars of normal masses. In addition, he has shown that the origin of the solar system is inexplicable by any existing tidal theory.

This is an excellent summary of our knowledge o stellar dynamics, and its value is enhanced by th references to all the workers on this subject.

M. D.

Intermediate Qualitative Analysis (Inorganic)

By Dr. A. J. E. Welch. Pp. iv+154. (London University Tutorial Press, Ltd., 1943.) 3s. 9d.

THIS book provides theoretical and practic instructions for the qualitative analysis of mi tures, and can be recommended for the use of student at the Intermediate and Higher Certificate stage.

An outline of the theoretical principles underlyin qualitative analysis is given first of all, and, apa from the use of the obsolete ferric-thiocyanat equation for the illustration of the law of ma action, it is quite adequate. There then follows a excellent chapter on the preliminary tests, apparatu and experimental technique of analysis. Especiall clear instructions are given on the use of the blowpipe, platinum wire, etc., in the dry tests which a so frequently bungled by inexperienced students.

The reactions for the identification of metall radicals are described in sufficient detail, but it is great pity that they have been represented throug out by molecular equations and the opportunit thereby lost of emphasizing the ionic character most of them. The tests for acid radicals have bee arranged in a system of three groups which shou be easy to operate.

In the closing chapter the tests are summarized i a tabular form which should prove useful, especial as the correct quantities of the reagents have bee specified. A. C. C.

A New German-English Psycho-Analytical Vocabulary

By Alix Strachey. (Research Supplements to th International Journal of Psycho-Analysis, No. 1 Published for the Institute of Psycho-Analysis.) P v+84. (London: Baillière, Tindall and Cox, 1943 10s. 6d. net.

DICTIONARIES are of use to many and a sourc of real joy to a few. To this small minority th present slim volume will prove additionally attracti through its excellent typography. It is, as the prefac states, essentially an enlarged and revised edition a glossary issued as a supplement to the *Internation Journal of Psycho-analysis* in 1924. It does no contain the interesting notes and comments appende to certain entries in the former work, but with th increasing standardization of psycho-analytic terminology in the intervening years these are no scarcely necessary. A good many terms that we being tentatively introduced at the earlier date hav now been generally adopted; for example, ‘para praxis’ and ‘cathexis’ (for *Fehlleistung* and *Besetzun* respectively). On the other hand, the word ‘u pleasure’ (for *Unlust*), formerly described as “hardl acceptable linguistically”, is now accorded th dignity of a technical term. Those who grumble a the ‘Freudian jargon’ will probably express ‘di pleasure’ at such terms as ‘scopophilia’ and ‘osphr siophilia’, but would they stomach ‘peeping’ an ‘sniffing’ any better? It is perhaps a pity tha Havelock Ellis’s more euphonious ‘eonism’ (o analogy with ‘sadism’ and ‘masochism’) is not give as an alternative to ‘transvestitism’.

J. C. FLUGEL.

A HUNDRED YEARS OF ANTHROPOLOGY IN BRITAIN

By SIR JOHN MYRES, O.B.E., F.B.A.

THOUGH the Royal Anthropological Institute was not founded until 1871, it is the direct successor of the Ethnological Society of 1843, after amalgamation with the Anthropological Society of 1863, and may justly claim now to celebrate, on October 30, the centenary of the organized study of man in Great Britain; and the main turning-points in the careers of these Societies illustrate the general course of events in a wide range of studies, from comparative anatomy of the principal human varieties to comparative religion, sociology and linguistics, and the whole range of the material arts with their archæological perspective, so nearly co-extensive with human palæontology.

At first sight this study of man is no systematic science, like chemistry or physiology, but rather analogous to geology and geography, which combine the methods and the data of more specific branches of knowledge for the elucidation of problems of a secondary order, and especially involving relations of distribution in time and space. But it has been characteristic of British anthropology to insist that the peculiar nature of man provides the same kind of common basis and definition for a coherent mass of information, and systematic study of this material by every available means, as the earth provides in geography—and not least because in geography, too, it is 'the earth as the abode of man' which seems to many geographers to differentiate between this study and geology or terrestrial astronomy. American anthropology has followed the same line of thought and development; partly because in the New World, as in the British Empire, there has been so great a wealth of opportunity for the regional study of more or less self-contained and self-determined varieties of mankind, so that analytical studies of structure, language, material and social equipment have been continually challenged and tested by fresh discoveries in the field; whereas in most European countries, less well provided with 'aborigines', the special sciences which contribute to the study of man have developed independently, and lost this common basis of humanity. It is also this common objective, which has given to much British and American work a disciplinary and educational value, and thus has at long last determined the position and function of the principal anthropological institutions and schools, as the outline of an academic discipline which might claim in due time to be *Literae humanissimae*.

Though both physical anthropology and the elements of ethnology, and what is sometimes distinguished as cultural anthropology, had long been studied discursively, in classical culture, and from the Revival of Learning, there were many convergent instigations to more systematic treatment in the early years of the nineteenth century. The Romantic Movement, and the Revolutionary Movement which emerged from it, gave the same impulse to human studies as to the physical sciences. In both the cry was 'back to Nature', at whatever cost to convention or authority. Anatomical studies reformulated old problems of the origin and significance of human races and varieties. Comparative philology indicated processes of modification and replacement among languages, and relations of heredity between them, seductively like those of a pedigree, and sometimes correlated regionally with major racial types, Semitic with Arab, and the like. The Danish archæologists combined typological classification of implements—stone, bronze, and iron—with the stratigraphy of the peat bogs where they were found, and especially with secular changes of flora and climate. Cave-finds in France and in England associated rude implements with 'ante-diluvial' fauna, and even with human remains. Comparative mythology, in dangerous alliance with philology, led on to the interpretation of social and political terms in kindred languages, to a comparative sociology, and to a 'linguistic palæontology'. The common factor in all these new studies was the notion of development and series of events in time.

There were other considerations, more practical and controversial; the abolition of slavery was a corollary of the Rights of Man within one human species. But what if, zoologically, there was more than one human species, of separate special creation and independent 'place in Nature', like that of the domesticable animals, over whom human dominance seemed to have biblical sanction. Was not *black* man, in fact, the 'natural slave' as defined in Greek philosophy? To some, the American Indian seemed to present a similar problem, as the economic expansion of the West went on. On both sides zoological arguments were brought in, to support philanthropy or to challenge vested interests, and it was long before this kind of 'applied anthropology' became obsolete.

There was also the practical question: What was to be done with the 'black brother' after emancipation? Was he improvable into something not so far from white? What was the relation between physical and mental characters in man, and what could be done to perfect Nature's work by scientific processes? It is significant that most of the early British anthropologists were practising medical men, and James Cowley Prichard, the most eminent, was a Commissioner in Lunacy, with a high repute in questions of the moral and legal responsibility of the insane. Several were also members of the Society of Friends, and Thomas Hodgkin was the founder of the Aborigines' Protection Society in 1838. Other philanthropic agencies, the Negro Emancipation Society and the British Africa Colonization Society (both of 1834), collected information and used it as best they could. Another foster-parent, for obvious reasons, was the British Phrenological Society.

The earlier history of the Ethnological Society has been so fully told elsewhere that only essentials are necessary here. It was never a populous or influential body, and owed its existence and successes to a small group of original and devoted men, nearly all in professional careers, and very few of them affluent. On many occasions the same persons appear as the active members of the geographical or zoological section of the British Association, sometimes in a specific subsection for ethnology; and this summer and winter partnership, never quite effected in any other section, makes the origin of some enterprises difficult to trace, except personally.

In 1839 Prichard addressed to the British Association a warning, already needful, on "The Extinction of some Varieties of the Human Race", and appealed for prompt and organized effort to record this vanishing material. It was the first of a long series of such appeals, to forestall both the disappearance of aboriginal communities altogether, and the no less fatal effects on aboriginal customs, of contact with colonists, traders, and missionaries. For the guidance of intending travellers and of observers already in contact with natives, the British Association appointed a committee to draft a pamphlet of "Instructions to Travellers", in which the whole programme of anthropological and ethnological research was set forth: an original and stimulating directory, and the immediate predecessor of the well-known "Notes and Queries in Anthropology" which have for many years been printed and reprinted by the British Association, but sold, and distributed to travellers, by the Anthropological Institute. It was the first example of a type of handbook of which the most famous is the Royal Geographical Society's "Hints to Travellers".

On June 22, 1842, Prichard again addressed the British Association "On the Relation of Ethnology to other Branches of Knowledge", with the outline of an inclusive programme of advanced study and objectives for research; and on July 20 the prospectus was issued for an Ethnological Society, signed by Richard King (1811–76), a pupil of Thomas Hodgkin at Guy's (M.R.C.S. 1832 and hon. M.D. of New York), who had been surgeon-naturalist to Capt. George Back's expedition to the Great Fish River (1833–35), and published a book on the Eskimo in 1844. The first meeting was held early in November, 1843, with King as secretary and Admiral Sir Charles Malcolm (1782–1851) as president. Malcolm had been superintendent of the Bombay Marine, the precursor of the Indian Navy; he had created a distinguished school of surveyors, and devoted much of his leisure to the Royal Geographical Society and to the organization of charities. Meetings were held in Hodgkin's house in Bedford Square, London, and in hired rooms at 27 Sackville Street, W., and both Hodgkin and Prichard seem to have been generous financially. The latter published his "Natural History of Man" in 1843, and died in office as president in 1848. Another good friend was James Crawfurd (1783–1868), who had used the opportunities of a medical career in India and Malaya and returned home in 1827 to devote himself to Oriental languages.

King returned to arctic exploration in 1850, wrote an inclusive account of the long search for Franklin (1855), published an account of the Lapps (1871), and lived to be a member of the first council of the Anthropological Institute.

Another pioneer, on rather different lines, was Robert Knox (1791–1862), who graduated in medicine at Edinburgh in 1814, served as army surgeon at Waterloo, studied in Paris under Cuvier (1769–1832) and Geoffroy E. Saint-Hilaire, and organized the Museum of the Royal College of Surgeons at Edinburgh (1825), collecting material under the adventurous conditions of the time. Passionate and heterodox, he gravely damaged his own prospects; he lectured volubly on the "Races of Man" in many places, and wrote copiously in the Press, rendering much erratic help to the Society, and became in 1860 an honorary fellow and honorary curator of its museum. He held strong polygenist views but deemed the origin of races to be beyond human inquiry. His influence, therefore, waned when Darwinian evolution was popularized.

Very different are two anthropological pioneers of the next decade. John Beddoe (1826–1911), of Bridgnorth, graduated in medicine from University College, London (1851), and studied in Vienna. Hospital service at Renkioi in the Crimean War extended his earlier studies of hair and eye colour (1846) to Mediterranean peoples, which he continued to observe in Bristol and Cardiff when he went into general practice. His massive material on "Stature and Bulk of Man in Great Britain and Ireland" (1870) and "The Races of Britain" (1885) has been supplemented but not replaced, especially by the British Association's Ethnological Survey Committee and Anthropometric Committee. He was an early and active fellow of the Ethnological Society and a foundation member of the Anthropological Society, and it was under his presidency of the latter (1869–71) that the schism was reconciled and the Anthropological Institute inaugurated.

George Rolleston (1829–81), combining classical scholarship with anatomical distinction, served, like Beddoe in the Crimean War, and as Linacre professor of zoology at Oxford amassed a valuable collection of crania, submitted his system of brain-classification to the British Association at Oxford (1860) and supported Huxley in opposition to Owen at Cambridge in 1862. His Royal Institution lecture (June 24, 1862) is another turning point. With William Greenwell ("British Barrows", 1877), he established the racial history of Britain on the same sure foundations as the racial distributions outlined statistically by Beddoe.

But the leading mind in ethnology during the Darwinian period was that of Thomas Henry Huxley (1825–95), whose learning, judgment, and skilled advocacy made him a second founder of the science in Britain, and moreover the leading spirit in an 'evolutionary' movement far outranging his own anatomical and zoological contributions. The notion of natural selection and survival of the fittest was applied to arts and crafts by General Pitt Rivers to archæology by John Evans and Augustus Franks to institutions by John Lubbock, above all in traditions, ideas and beliefs by Edward Tylor, whose establishment at Oxford (1883), through Rolleston's influence, was the first academic recognition of the new study of man.

The practical issue of American slavery revived old controversies and gave scope to the enthusiasms of James Hunt (1832–69), who joined the Ethnological Society in 1856 and was its secretary during 1859–62. Fresh light on the origin of man came from the palæolithic discoveries of Boucher de Perthes, verified by Prestwich and John Evans in 1859; the Neanderthal skull had been found in 1857, and the cave of Aurignac was opened in 1860. But Hunt's enthusiasm failed to rouse the Ethnological Society, and in 1863 he founded the Anthropological, edited the *Anthropological Review*, and published translations of Waitz and Gerland, the leading ethnologists in Germany, and of Gastaldi on Swiss and Italian lake dwellings. The Anthropological Society loved discussions and ranged far afield, to woman's rights, the Irish question, and above all the Negro question. Its first chairman was Sir Richard Burton. Hunt defended slavery, on the old zoological ground of a plurality of species, at the British Association in 1863, where with Huxley's support a subsection was established for anthropology in 1866 under Section D (Zoology). But Hunt was combative and difficult; he resigned the presidency of his Society in 1867, but remained its 'director' until his premature death in 1869.

The way was now open for reconciliation. The Negro question had been settled by the American Civil War; Huxley in the chair of the Anthropological Society, and Beddoe of the Ethnological, rallied men of goodwill on all sides, and in 1871 was established the Anthropological Institute of Great Britain and Ireland with Sir John Lubbock as its first president. With the financial help of the British Association, the revised "Notes and Queries in Anthropology" were published; the Anthropometric Committee of 1875 gave much needed definition to physical anthropology; and its annual measurements of the members of the British Association did much to popularize statistical treatment of its problems. Organized by Francis Galton, this was the precursor of the Galton Laboratory at University College, London, and of the systematic study of biometry and eugenics in Britain.

When the original library and museum, at 4 St. Martin's Place, W.C.2, were pulled down, the good offices of the president of 1883–85, William Henry Flower, secured an appropriate home in the upper part of the Zoological Society's house at 3 Hanover Square. This arrangement, however, was nearly disastrous to both institutions, for the weight of exhibits from the first excavation of Stonehenge (1901–2) irretrievably damaged the building and hastened the transfer of the Zoological Society's offices to Regent's Park. By this time the close association of the Institute with the ethnological staff of the British Museum, inaugurated by Augustus Franks and extended by Charles Hercules Read and others down to the present time, drew the Institute into a succession of abodes in Bloomsbury, the last of which, 21 Bedford Square, is within a few yards of the original meeting room in the house of Thomas Hodgkin.

Of the mature work of the Institute only outlines are possible here. Like its predecessors, it has never been rich, and has owed much to benefactions supplementary to its normal income; from the Carnegie Trustees for the improvement of its valuable library, from the Rockefeller and Laura Spelman Rockefeller Foundations to maintain its *Journal*, and from other friends for a few small expeditions. But it has never had the popular appeal of the Zoological or the Royal Geographical Society, or the support of academic or industrial interests. Side by side with its proper business of the promotion and publication of research, it has never ceased to urge on the Colonial Office and other public agencies the pressing need for expert acquaintance with the customs and mode of life of the native peoples of the British Empire; but until recently with disappointing response, in comparison with stately institutions such as the Colonial Institutes of the Netherlands and of Belgium, and the Bureau of Ethnology in Washington. Even the urgent task of recording institutions and modes of life which have been fading away before our eyes has been postponed irretrievably. The inevitable dissipation of energies in specialist societies has been minimized by the establishment of research committees within the Institute itself, for India, Africa, Anthropometric Standards, and the like, and of a Joint Committee for Anthropological Research and Teaching, on which universities and independent institutions are entitled to be represented, which has no parallel in other branches of learning in Great Britain. In the generation following the war years 1914–18, as the spokesman of that Joint Committee, the Anthropological Institute has twice taken decisive part in the organization of the International Congresses for Prehistoric and Protohistoric Sciences (London 1932, Oslo 1936) and for Anthropological and Ethnological Sciences London 1934, Copenhagen 1938), which have provided at least the constitutional foundations for worldwide co-operation on liberal lines in time to come.

ACTIONS OF DRUGS

ABOUT two hundred and fifty persons attended a discussion in London on September 24 organized by the Faraday Society and entitled "Modes of Drug Action". The meeting lasted six hours and a wide ground was covered by the papers, which had been circulated in proof. These papers contained much interesting matter and it was perhaps unfortunate that too large a proportion of the available time and energy of the meeting was devoted to listening while they were expounded. In the following account the order in which the papers were given has been altered.

Prof. E. K. Rideal, who took the chair, paid a tribute to Sir William Hardy, who was responsible for initiating these joint discussions between biologists and physical chemists. Sir Henry Dale, in his general introduction, stressed the complexity of the problems of pharmacology and warned the meeting against the optimistic adoption of simple theories to explain complicated facts. Most of the generalizations that have been made have exceptions, and it is on these that attention should be focused.

Prof. J. H. Gaddum discussed the antagonism of drugs, and the quantitative relations between the antagonists. It is important to distinguish two kinds of interaction, both of which may give rise to graded antagonism over a wide range of concentrations. Some antidotes neutralize poisons by forming inert compounds with them, as SH- compounds do with mercury. In this case the study of the antidote throws no light on the action of the drug on the tissue. Its action is merely to reduce the concentration of free poison present.

Other antidotes act by competing with poisons for chemical groups essential to living tissues. The study of these is more interesting, since it allows drugs to be classified according to their antagonists, and may provide evidence about the particular chemical processes in the cell with which the drugs interfere. The work of Woods on the antagonism of sulphanilamide and *para*-aminobenzoic acid is a striking example of work in this field. The quantitative relationships between antagonists were discussed. If the reactions are of the first order, the ratio of the concentrations of the two drugs which together produce a given effect should be constant, provided that the concentrations of one drug are calculated as differences from the threshold concentration. This is true whether the drugs neutralize one another or compete, so that it is impossible to distinguish the two kinds of antagonism except from independent evidence that the drugs either combine with one another or have molecules which would be likely to combine with similar groups in the tissues.

Dr. H. R. Ing discussed the theory that drugs combine with specific receptors in tissues and the extent to which it can be used to interpret the relation between chemical constitution and pharmacological action. When a series of allied drugs is studied, it is often possible to recognize pharmacodynamic groups which appear to be essential for one particular type of action. It might be said that this group is essential for combination with the receptors, but there are anomalies. The same pharmacodynamic group is commonly present both in active drugs and in their antagonists. The results can be explained in terms of competition between the two drugs for the receptors, if it is assumed that one of them causes an active response and the other blocks the receptors but causes no response. Since drugs with a feeble action do not antagonize drugs with a greater action on the same receptors, the response must depend only on the amount of drug combined with the receptor and not on the magnitude of its effect when so combined, which must be all or none. The receptor theory provides a useful intellectual framework for the consideration of the qualitative aspects of the problems presented by the structure and action of drugs. We do not know enough of the receptors to predict the effects of minor changes in the molecule.

The relations between *in vivo* and *in vitro* actions of chemotherapeutic agents were discussed by Dr. H. McIlwain. He gave an able summary of the extensions of the theories of Fildes and Woods which have enabled him to discover new types of therapeutic agent by using substances similar in chemical structure to the normal metabolites of bacteria. The results obtained in the body are complicated by variations in the concentrations of antagonistic substances, and by the actions of the body on the drug and the drug on the body. These interactions are not always the same in different species of animal and under different conditions, and a complete picture can only be attained by correlating observations on whole animals with those obtained *in vitro*.

Sir Rickard Christophers gave an account of work on the metabolism of the malaria parasite, which consumes oxygen at a high rate ($Q_{O_2}=35$) and utilizes glucose if it is present, but can utilize various other foodstuffs in the absence of glucose. Drugs which are used in the treatment of malaria inhibit the oxygen consumption when they are present in concentrations such as may occur in the blood in treatment. This work provides an opportunity for studying the action of these drugs *in vitro*, and so measuring the activity of drugs, without having to consider the complicating effects of differences in their rates of absorption and excretion.

Dr. E. M. Lourie discussed the failure of some arsenical drugs to penetrate the blood-brain barrier and so to act on trypanosomes in the brain in the late stages of sleeping sickness. The best method of studying this problem is probably the estimation of the trypanocidal power of the cerebrospinal fluid when the drugs are administered; but even then, drugs may reach the fluid through the choroid plexus without ever coming in contact with the brain cells. There is some evidence that acid compounds penetrate the barrier more readily than basic or neutral compounds.

The relation between the chemical structure of organic arsenicals and their combination with trypanosomes was dealt with by Dr. H. King. He divided these drugs into three classes; some, like phenylarsenoxide, are active because their properties make them concentrate at lipoid interfaces; some, like atoxyl, show large differences in their actions on normal strains and drug-resistant strains of trypanosomes, and these probably combine with the organism in the same way as acridine dyes; others, like phenyl glycine arsenoxide, are probably not concentrated in the organisms at all. These factors control the combination between drug and organism. The subsequent action of the drug probably depends on quite other factors, such as a combination with SH- groups.

Dr. J. H. Quastel discussed the action of narcotics, and of amphetamine, on the central nervous system. Narcotics reversibly inhibit the oxygen uptake of minced brain, or of brain slices, in concentrations similar to those occurring during anæsthesia in the whole animal. The effect is most marked when the substrate is glucose, and is almost absent when the substrate is succinate. They also specifically inhibit glycolysis in other tissues; but there is evidence that the brain is particularly dependent on glucose metabolism, and that may be why the brain is particularly susceptible to narcosis. Tyramine, and some other amines, cause a diminution of the respiration of brain, which increases with time and is due to an aldehyde formed from tyramine by amine oxidase. It is suggested that the wakening effect of amphetamine, and other amines which inhibit amine oxidase, is due to inhibition of the formation of aldehydes, which are normally present and which normally cause a partial depression of the central nervous system.

Prof. F. Weigert described experiments on the fate of benzpyrene in the body. The long latent period in the carcinogenic action of this substance raises the question whether it persists throughout this time as such, or is changed into some other carcinogenic substance. The substance itself and some of its products in the body can be detected by their fluorescence and purified by chromatography. One of these products is particularly liable to collect in the tissues where cancer is liable to occur, and may be the immediate cause of the cancer.

Prof. E. K. Rideal discussed the general question of the combination of drugs with tissues in terms o electron chemistry. The forces involved are complex and can profitably be studied by measuring the energy of adsorption of drugs on proteins, by the chromatographic method and by putting drugs in solution beneath monolayers in a trough. The application of these methods to pharmacologica problems is still in an embryonic stage, but holds the promise of explaining the behaviour of drugs in terms of the detailed constitution of their molecules.

Dr. J. H. Schulman emphasized these views by giving actual examples. It has, for example, been shown that the lytic activity of a series of surface active long-chain paraffin ionic salts bears relation only to their surface activity at a cholesterol o protein interface, and in no way to their effect on the surface tension at an air-water interface. The optimum activity of synthetic oestrogens is correlated with their adsorption at a protein interface. Th adsorption of proteins causes precipitation of lipoid emulsions provided that the charge on the protein i the opposite of that on the emulsion. The effects o using emulsions with different charges, and different proteins at different hydrogen ion concentrations can be successfully predicted from this theory.

Dr. H. Hurst spoke at some length of the actions of drugs on insects, and emphasized the fact tha when the drug is applied to the outside of the insec its action is very much influenced by the permeabilit of the cuticle. His views on this subject have recentl been published in NATURE (**152**, 292; 1943).

Three papers from the Physical Chemistry Labora tory at Oxford described studies of the growth o *B. lactis aerogenes* in artificial culture. There i normally a lag-phase followed by a phase of exponential growth, and the growth then slows u again and the population eventually becomes con stant. Dr. R. M. Lodge and Prof. C. N. Hinshelwoo described the adaptation of the organism when it i transferred from bouillon to a simpler syntheti medium. In the first few subcultures growth is slow and abnormally long, snake-like cells are formed. I is concluded that separate mechanisms, responsible for (*a*) the removal of growth inhibitors, (*b*) elongation and (*c*) division, become adapted at different rates to the new medium.

Dr. G. H. Spray and Dr. R. M. Lodge described the effects of resorcinol and *m*-cresol, which cause a prolongation of the lag rather than a slowed rate of growth, or a diminution of the stationary population. Resorcinol is eventually completely inactivated by the bacteria, but *m*-cresol is not. Long, snake-like bacteria can be produced by *m*-cresol under certain conditions. Dr. D. S. Davies and Prof. C. N. Hinshelwood described the effects of sulphonamides, which both increase the lag and reduce the growth-rate, but do not inhibit growth completely even in high concentrations. On subculture in the presence of sulphonamides the organisms become immune to the drug. Thus immunity is at first partial, reversible and specific to the particular sulphonamide (sulphanilamide or sulphaguanidine) used. After thirty subcultures it becomes complete, irreversible and unspecific. The theory that this is due to the selection of resistant organisms is rejected, and it is assumed that the cells develop enzymes which produce a sulphonamide antagonist. The partial antagonism which develops earlier is probably due to other causes.

A full account of the meeting will appear in the *Transactions of the Faraday Society*.

J. H. GADDUM.

AREA HEATING

THE publication of recent technical papers* on so-called district heating emphasizes a grave omission in the County of London Plan; indeed, the term is mentioned a few times, but there is no consideration of the very great contribution this development of applied science can make, on several grounds, to the social development of large population groups which have arisen in Great Britain, especially the conurbation of London. The subject is very briefly mentioned in the exhibition of planning now open at the Institution of Civil Engineers, held jointly by that body and the Institution of Municipal and County Engineers. Twice in the last twenty years St. Marylebone Borough Council, which generates its own power, discussed supplying the local housing estates with heat, but failed to grasp the opportunity of obtaining experience in this field.

There is a ray of hope, however; Coventry has just agreed to incorporate district heating in its reconstruction programme. The local authority still has to convince the Electricity Commissioners, and then bring a Bill before Parliament. Further, the Public Works Committee of Bristol has had submitted to it a plan to cover the central area of that city.

The major public difficulty is that the existence of district heating is not obvious. It is not like a railway, bridge, or power-transmission line, which anyone can observe or appreciate for use or value. District heating is not known in Great Britain, whereas it is a national policy in the U.S.S.R.; Russian schemes already dispose of more heat than is conveyed by all the town-gas in Britain. Hamburg has had it on an increasing scale for half a generation, and each of the latest German schemes is larger than the New York plant, which uses 775,000 tons of coal annually.

What, then, are the virtues of district heating? Practically all electric power in Great Britain is generated by high-pressure and high-temperature steam, dropping its entropy in turbo-generators. The maximum working efficiency of energy conversion from coal to electricity is not likely to exceed 30 per cent in the most modern, and consequently all new, power stations; it averages 20–25 per cent. The major loss is in the condensation of the steam at low-pressure, necessary for the operation of steam turbines; that is, the latent heat is wasted. In other words, every large power station is throwing away a million kilowatts continuously into the local river or its cooling towers.

The usage of electric energy is increasing at a rapid rate, and in many large places, which provide centres of gravity of electric loading, new power stations will be required. London after the War will, it is probable, require several new power stations or great extensions to cope with the increasing load. The more electric energy is used under the present system, the more coal energy is wasted. The natural and obvious proposal is to utilize this wastage of heat for domestic and process work in the neighbourhood of these power units.

Continental practice shows that a distribution of this waste heat is easily economical up to seven miles, and, in favourable circumstances, several times this. It is calculated that with reasonable capital expenditure, which can be amortized in between five and fifteen years, depending upon the particular circumstances, such heat can be sold at not more than 4*d*. per therm; this would make important contributions to coal conservation.

A more attractive scheme is to burn the coal in boiler stations, in which can be realized efficiencies of conversion up to 90 per cent, on the rim of large centres of population, transmit the steam through large pipes to turbo-generators located at the centre of gravity of the electric load, and dispose of the heat, which otherwise would be wasted, in the surrounding domestic and industrial areas. The wastage of heat in such pipe transmission is of the order of 1 per cent for seven miles, because of the very large diameter required; the pipe need not be lagged with heat-conserving material. In one step we save the expensive area required for a coal depot essential now to every power station, the consequent dirt which arises from coal and ash handling, and any more which is permitted by expensive smoke cleaning plant to escape through unsightly chimneys; we have saved not only the cost of expensive condensing plant, and cooling towers on non-river sites, but also, in the latter case, expensive ground and the enormous amount of condensation which is inevitable in their region during humid weather. The problem of noise arising from generators in a comparatively small building can easily be coped with by modern methods of noise control.

Having decided to dispose of hitherto wasted heat—and it may be remarked that it is not possible to extract much heat from existing power stations because the full benefits are not realizable without special designs of back-pressure turbines—the problem is to distribute such heat in the form of hot water or steam at high pressure to the situations where it can be utilized. Naturally, the regulation of demand, which would not be exactly in step with the electric power demand, causes some difficulty, but this can be overcome by having adjustable back-pressure on the turbines with suitable heat-reservoirs, these taking the form of lightly heat-insulated steel water-towers; the pipe-lines would be tapped to convert the heat through thermostatically controlled calorifiers in consumers' premises. The County of London Plan, with its new roads, both radial and ring, offers not only suitable routes for the large piping which would be required for the main heat transmission routes, but also, since these routes go through areas which are intended for planning on the ten-story-block-of-flats principle, the latter could be designed immediately for district heating with a minimum of capital expenditure, thus saving valuable boiler accommodation and fuel storage.

---

* *Electrical Times*, Sept. 30 and Oct. 14, 1943; *Engineering*, Oct. 8, 1943; *Industrial Heating Engineer*, July–Oct. 1940.

With regard to competitive forms of heating, the Engineers' Study Group on Economics, collecting information from many organizations, had previously deduced that it is in the national interest to use gas rather than electric power for basic domestic heating, the point being that if large sections of the population could be persuaded to abstain from wastefully using soft coal in domestic hearths and to use coke or other low-temperature carbonized coals instead, it will be necessary, in order to provide such hard fuel at reasonable cost, economically to get rid of great quantities of the minimum gas which is necessarily involved in producing any specified quantity of hard fuel. Prof. C. L. Fortescue, in an informal discussion at the Institution of Electrical Engineers, also arrived at the desirability of increased domestic heating by gas from other arguments. Thus there is competition on technical, social, and economic grounds between district heating by waste-heat from power stations, and domestic heating by means of gas. Electric power is so precious and high-grade that it must be considered out of the question for basic domestic heating, except in special circumstances.

A further reason for the usage of gas for basic domestic heating is the technical one of regulation. It is well known that in suburban areas in which domestic gas-cooking is prevalent, the drop in pressure at the peak-loading, especially for Sunday dinners, is serious. It is therefore desirable to use electric power for cooking, because of its high regulation, which is also essential for lighting and normal power requirements. We are thus led to conclude that electric power should be reserved for those applications where good regulation is desirable, and gas should be used where, through automatic control, such as in gas central heaters, which have been hitherto little used in Great Britain, close regulation is not essential.

What case, therefore, can be made for district heating? It must be based on the fact that electric power is increasingly demanded, and therefore there is a waste of energy, as explained previously. It follows, therefore, that in the national interest district heating should be used where practicable and economic, the gaps being filled by gas. Electric power should be reserved for those applications where it is most effective, such as electric traction, electric lighting, and the manifold large and small power uses where its delicacy of control gives it an advantage over any other competing form of power.

On social grounds, district heating would, at one stroke, if carried out on a large scale in large centres of population, dispose of the necessity of the traditional domestic fire and the consequent wastage of heat into the open sky, the pollution of the atmosphere with unconsumed carbon, and the wide-scale deterioration of buildings because of the sulphur acids emitted into the atmosphere. The point here is that whereas in large power stations the exhaust gases can be cleaned efficiently, or so dispersed in countryside areas that their effect on man and Nature is substantially zero, there can be no such control over the tiny combustions which occur, to the number of millions, in domestic premises. The general adoption of central heating which has taken place in other countries may not be desirable in Great Britain; in fact, the ideal for our more moderate but erratic climate would be semi-central heating, topped up with a small amount of radiation, gas or electric. In this way the great value of our climate—its variability between extremes which are small in comparison with climates in other parts of the world—is conserved, both indoors and without.

L. E. C. HUGHES.

OBITUARIES

Mr. A. C. Gardiner

ALAN GARDINER died on August 29 at the age of forty-six. The news came as a great shock to his many friends, and hydrobiology suffered a severe loss He was educated at Oundle and Gonville and Caius College, Cambridge, and inherited a love of science from his brilliant father, the late Dr. Walter Gardiner. As soon as he had graduated in 1920 he began the line of research which always continued to attract him: the problems of plankton ecology, sometimes freshwater, sometimes marine, and refinements in the methods of attack. This work, although broken by periods of illness, was always taken up again, and he was actively pursuing it at the time of his death.

His first investigations, in collaboration with the late Mr. Rowland Southern, were made over severa years from a floating laboratory on the River Shannon where it flows into Loch Derg. The amount of data they amassed, biological, physical and chemical, was enormous; in studying the diurna migration of the animals they at times kept up their sampling and recording at intervals through the day and night for a week or more on end. The working up of all this material took many years, and their splendid studies of lake and river plankton appeared at intervals from 1926, long after the field work was completed. Southern died in 1935, but Gardiner finished the great work in 1938.

Leaving Ireland, Gardiner was appointed in 192 to the research staff of the Ministry of Agriculture and Fisheries and took up the problems of freshwater biology in relation to pollution at the ministry' laboratory at Alresford. Here came his first serious breakdown in health, and he was forced into exile to Switzerland. On his return he joined the marin Fisheries Laboratory at Lowestoft and devoted himself to such problems as the effects of patchiness in distribution upon the validity of plankton sampling the quantitative efficiency of nets and the vertica distribution and migration of plankton animals Ill-health forced him to resign and go back t Switzerland where, as he wrote in a letter, he wa teaching "Chemistry, Mathematics, 'As you like It' and 'The Acts of the Apostles' in a school for backward boys".

Better once more, Gardiner was appointed in 193 to the staff of the Metropolitan Water Board an threw himself enthusiastically into seeking solutions to the many problems of waterworks biology. H was particularly concerned with the factors underlying the incidence and duration of the diatom outbreaks which are often of such serious consequence in the clogging of filter beds. Having shown that their rate of growth could only be correlated with abundance of phosphate and silicate in the early part of the season, he was investigating the causal conditions acting later in the year. At the time of his death he was experimenting along several new lines of diatom culture and improved methods of estimating populations.

Gardiner never lost his interest in the sea. Thinking that animals must materially alter the phosphate content of the water by their excretion, he took a brief busman's holiday on the research ship *George Bligh* and, by the simplest experiments, with live plankton animals taken straight from the sea, at once proved his contention. This important factor in marine ecology had hitherto been completely overlooked, and much more will be heard of it in the future.

Gardiner's work had a splendid quality. After reading the late Sir Arthur Hill's account of his father ("Obituary Notices of Fellows of the Royal Society", vol. 3, 1941), one realizes that he inherited not only his love of biology but also his keen faculty of self-criticism and clear thinking; he was always striving after improved methods and greater accuracy. His most recent paper, published since his death, s typical of him: a critical examination of the pigment extraction method of measuring phytoplankton production.

I cherish many memories of him: of sharing a study at Oundle, of natural history expeditions with him both at school and in the holidays, of grand days together at sea on the *George Bligh* and latterly of his happy married life in London. From his early school days he was a martyr to asthma, to an attack of which he finally succumbed. All his life he battled with his health, but for ever made light of it. What a spirit he had, what courage, what a grand sense of humour! From a sanatorium in Switzerland he was a frequent contributor to *Punch*. When things must have looked their blackest his letters still sparkled with fun. He will be missed by so many, missed for his cheerful good company, for his intellectual honesty and for his sound reliable work. But for his ill-health how much more he would have done; in spite of it, how astonishing that he did so much! It is good to learn that the Freshwater Biological Association is to assist in the bringing of his unfinished work to publication.

Our sincerest sympathy goes to his wife and to his mother. ALISTER C. HARDY.

Prof. A. A. Read

ARTHUR AVERY READ was born at Honiton, Devon, in 1868 and died at Bournemouth on September 24, where he lived after his retirement from a tenure of forty years of the chair of metallurgy in University College, Cardiff. He was educated at Exeter Grammar School, Owens College, Manchester, and at the University of Sheffield (then the Technical School), where he studied metallurgy under the late Prof. J. O. Arnold. He went to Cardiff from Sheffield in 1894 as the first lecturer in metallurgy, and on his retirement in 1933 he had completed his life's work by the establishment of a department worthy of the University of Wales, housed in a modern building, which had been erected with the financial assistance of the Monmouthshire and South Wales Coal Owners' Association.

Read's enthusiasm for his work was such that the new department flourished, and he had the distinction of training the first man to obtain a B.Sc. degree qualification in metallurgy in Great Britain. Many of his former students have become distinguished men in the metallurgical world.

Read realized that a university has a two-fold obligation—not only to teach but also to prosecute original research; and he managed to keep an even balance between these two while at the same time he worked hard to build and equip his Department. His research work, in collaboration with Arnold, on the chemical relations of carbon and iron with various other elements such as manganese, chromium, vanadium, tungsten, cobalt and molybdenum, which were published over a period of years from 1895 until 1915, have proved of great value in the development of modern alloy steels. His interests in non-ferrous metallurgy resulted in the publication of several papers dealing with alloys of nickel, aluminium and copper, work with which Dr. R. H. Greaves was associated.

Outside College, Prof. Read was interested chiefly in the Volunteers and Territorials, and he received the Territorial Decoration. During the War of 1914–18 he was away from College on national service. After the War the University of Wales, and the College at Cardiff, both young institutions, were faced with serious problems, and Read sacrificed his personal inclination to resume his researches and applied himself energetically to University affairs. He brought to bear on academic matters an administrative outlook which was of inestimable value. His work was recognized by the University conferring on him the degree of D.Sc. *honoris causa*.

Read, always an inspiration to his students, won their respect for his straight dealing and then their affection for his kindliness and his readiness to champion their cause. W. R. D. JONES.

Mr. F. Napier Sutton

FREDERICK NAPIER SUTTON, a former alkali inspector in the Ministry of Health, died on September 24, aged eighty years. He was the eldest son of the late Mr. Francis Sutton, public analyst of Norfolk and Suffolk, and the author of the text-book "A Systematic Handbook of Volumetric Analysis".

Mr. Sutton was, for a very long period, works chemist to Messrs. Baily, Sutton and Co., of Great Yarmouth. In 1885 he was appointed assistant to the chief inspector (the late Alfred Fletcher) under the Alkali, etc., Works Act; he was promoted to sub-inspector in 1892 and to inspector in 1908. He retired on reaching the age of sixty-five in December 1927, having then served for forty-two years, during thirty-five of which he was in charge of the London and south-eastern counties district.

After his retirement and, indeed, up to the time of his death, he continued to take a great interest in the affairs of the Alkali Works Department of the Ministry of Health and in chemical industry generally. During 1892–1916 he was secretary of the London Section of the Society of Chemical Industry.

Mr. Napier Sutton was devoted to chamber and orchestral music, and for many years he was a player in some of the leading amateur orchestral societies. He was an expert trout fisherman, and a gifted 'dresser' of trout flies. He was greatly beloved by all his colleagues, and his passing will be widely mourned.

NEWS and VIEWS

U.S.S.R. Academy of Sciences

At a recent meeting of the Academy of Sciences of the U.S.S.R., thirty-six new academicians and fifty-eight corresponding members were elected. Among the chemists elected were Profs. Dubinin and Nesmeyanov, who have studied the chemistry of metallo-organic compounds, also Profs. Rodionov and Chernyayev, the well-known organic chemists. The geologists included F. Savarensky, a geologist who did valuable work in connexion with the construction of the Moscow–Volga Canal and the Moscow underground railway; Prof. Belyankin, a leading petrographer, who has helped greatly the industrial development of the Urals; Prof. Smirnov, a leading mineralogist of the Leningrad Mining Institute; and Prof. Satpayev, who represents the Kazakhstan branch of the Academy. Among the physicists were Lebedev, the well-known experimental physicist; Khristianovich, who has made investigations in mechanics; Alikhanov, who has studied the physics of the atomic nucleus; and Kurchatov. The biologists included the botanist Sukachev, the histologist Zavarzin and the Ukrainian pathologist Strazhesko. On the applied side, Major-General Blagonravov was elected to the Department of Technical Sciences, as were A. Mikulin, A. Yakovlev and V. Klimov, designers for aviation. The inventor of a new gun, A. Kostekov, was elected and also the Ukrainian economist, M. Ptukaha, who is charged with reconstruction duties.

Post-War World Education

Dr. Grahame Clark has an article in the September issue of *Antiquity* in which he attempts to integrate the various subjects to be taught in schemes for post-war education round the central idea of the evolution of mankind and his place in the universe. In other words, prehistoric anthropology—the study of our common origins—is to be the cement which will bind together the common education of the post-war nations of the world. The article is very interesting and thought-producing, and should be read by all concerned with post-war education. Considered on a university level, there is much to be said for Dr. Clark's thesis; whether his conceptions can possibly be adapted to the primary levels of teaching—to the brain of the child who is necessarily occupied with such problems as the writing of his own language correctly and the doing of his sums—is quite another matter. For, after all, education is not entirely 'book learning'.

Few to-day would deny that the twofold purpose of every educationist concerned with the upbringing of both children and adolescents is, first, to teach them how to live, and secondly to stimulate their interest in and to impart knowledge. Carrying the matter a stage further, the first of these can be subdivided into (1*a*) the art of living alongside one's neighbour, and (1*b*) the power to stand four-square with a reasonable personal independence ***vis-à-vis*** the material world. It is especially in this connexion that the various youth organizations play such an important part, and quite frequently and rightly are closely connected with the schools. The other object of education can be subdivided into (2*a*) the imparting of information useful for technical purposes, for the job in life to be undertaken by the individual, and (2*b*) the imparting of purely cultural information. (Naturally 2*a* and 2*b* often overlap. What is of technical importance for one man may be of purely cultural interest to another—the professional geologist may be interested in Plato, while the classical teacher may have a private passion for geology.) It would appear that it is only with 2*b* that Dr. Clark is in the main concerned. Unfortunately, in the past it has been just this side of education that has least interested the average Englishman, though to-day those who are actively keen on education can detect a change in this respect. There is no doubt that our curricula need an overhaul, and Dr. Clark's plea for prehistory and anthropology as basal subjects should be borne in mind.

District Heating in New York

Current discussions on fuel economy and planning for the future give a special interest to details recently published (*Steam Engineer*, **12**, 222; 1943) of the largest district heating scheme in the United States In the new Parkchester residential community in New York, the central heating of a whole building from one boiler plant gives place to the central heating of a whole district from a single boiler house The site for this vast scheme is an area of 129 acres occupied to the extent of 26·4 per cent of buildings 21·2 per cent of avenues and 51·4 per cent by lawns and walks. Accommodation for 40,000 people is provided in the 42,464 rooms of 51 blocks of flats, along with garages and a theatre. The central boiler plant, housed in a building 180 ft. × 75 ft., and including a chimney more than 300 ft. high, consists of four oil-fired boilers. From these the live steam is circulated on the return condensate system in a vast closed circuit. Instead of fitting a valve on each radiator in a room, a damper is used to control the heat. By this means leakage of air into the closed circuit through a multiplicity of valves is much reduced. The outside walls of each building are heavily insulated by a 1-in. thick spun glass layer together with a layer of air between the brick and plaster of the outside walls. This extra insulation alone is claimed to save £8,000 worth of fuel in a year Details are not given of the thermal efficiency o the transmission system. As the last building was ready for use in 1941, the whole scheme will have had a thorough trial by the time post-war reconstruction begins. The average cost to the individual is abou £2 15*s*. per month per room including heat and light and the flats, consisting of from two to five rooms are designed for people whose income is from £360 to £900 a year.

Medical Research in War-time and the Relie of Suffering

Two recent addresses are deserving of attention in that they deal with new advances in medical research. One is Sir Edward Mellanby's Ludwig Mond Lecture, devoted to a review of medical research in war-time (*Brit. Med. J.*, Sept. 18, 1943); the other is Sir Henry Dale's Frederick Price Lecture (*Brit. Med. J.*, Oct. 2, 1943) on the remarkable recent advances in chemotherapy, all of which have been made in the comparatively short interval between the War of 1914–18 and the present War. Sir Edwar Mellanby refers to "endless references in religious theological, and even philosophical addresses", to the prostitution of science, especially for the purpose of war, and to "some suggestion that there exists in science and scientific men a kind of wickedness not shared by the humanities and by those engaged in their study". This kind of tilting at science is familiar enough. It springs from a failure to recognize that science is neither good nor evil; it is man who uses science for his good or evil ends. No one who reads these two addresses can avoid the conclusion that science can be, and is being, used for wholly beneficent ends and that countless men and women all over the world, as well as countless technicians who assist them, are devoting their lives to the betterment of the lot of humanity and sometimes are losing their lives in this service.

Sir Edward Mellanby's address deals with the organization and duties of the Medical Research Council and with organized medical research on blood transfusion, nutrition, problems of drug supply, the emergency public health laboratory service and the application of medical research to the needs of the fighting services. He inevitably makes contact, through his references to the sulphonamide drugs and to penicillin and other antiseptics, with Sir Henry Dale's more detailed history of these and other pharmacological discoveries. Sir Henry points to future fields of work and to still more remarkable benefits to come. We live, it is clear, in one of the greatest hours of medical history. The depreciators of science should consider, after reading these two records of lives saved, suffering reduced and hope for a better future securely established, whether science, properly used, is not one of the greatest of the humanities. Has any other human activity brought, in so short a time as the interval between the War of 1914–18 and that of to-day, so much effective and practical aid to the sick, the distressed and the broken in mind and limb ?

Glaxo Laboratories' Products

THE flavines or amino-acridines have long been known as antiseptics that are particularly effective in the presence of serum, which diminishes the activity of most other antiseptics. Acriflavine, which is the one generally used, has also trypanocidal powers, hence the name trypoflavine. Glaxo Laboratories, Ltd., of Greenford, Middlesex, have just introduced 2 : 7 diamino-acridine hydrochloride and 5 : amino-acridine hydrochloride. The former is stated to have the least toxicity of all the flavines, and, while not interfering with healing, to be rapidly bactericidal. It is effective against certain Gram-negative organisms not affected by other acridines in similar concentrations. The latter is a non-irritant antiseptic with an anti-bacterial activity similar to that of other flavines and has the advantage of not staining the skin.

Other products which this firm is introducing are nicotinamide, which possesses a similar therapeutic value to nicotinic acid without producing the uncomfortable flushing and other skin reactions so common with the acid, and Suspended T.A.B. Vaccine (synthetic culture medium). It is stated that by using a synthetic culture medium free from the protein and other substances contained in the usual bacteriological broth and nutrient agar, reaction from the use of such substances is avoided. The full antigenic properties of the organisms are retained, while the absence of protein from the culture medium restricts the reaction to that produced by the bacteria themselves. It is claimed that the reactions from this T.A.B. vaccine are few, principally of local pain and stiffness at the site of the injection, while the antigenic response is extremely satisfactory.

Colonial Fisheries Advisory Committee

THE Secretary of State for the Colonies has appointed a Colonial Fisheries Advisory Committee to advise him on problems concerning fisheries (marine and freshwater) in the Colonial Empire, in association with his fisheries adviser. The committee is constituted as follows : The Duke of Devonshire, Parliamentary Under-Secretary of State for the Colonies (*chairman*); Mr. G. L. M. Clauson, Colonial Office (*vice-chairman*); Dr. S. Kemp, director of the Marine Biological Association of the United Kingdom ; Dr. E. B. Worthington, director of the Freshwater Biological Association of the British Empire ; Dr. E. S. Russell, fisheries adviser to the Secretary of State for the Colonies ; Dr. G. A. Reay, director of the Torry Research Institute (Department of Scientific and Industrial Research), Aberdeen ; Dr. B. S. Platt, in charge of investigations into nutrition in the Colonial Empire under the Medical Research Council ; Mr. J. R. Norman, deputy keeper, Department of Zoology, British Museum (Natural History) ; Dr. C. F. A. Pantin, reader in invertebrate zoology, University of Cambridge ; Mr. R. S. Wimpenny, naturalist, Ministry of Agriculture and Fisheries ; Mr. J. Thomson, chief inspector of fisheries, Ministry of Agriculture and Fisheries ; Mr. Morley Neale, member of the firm of Messrs. Neale and West, steam trawler owners, Cardiff ; Mr. C. N. Hooper, clerk of the Fishmongers' Company ; Mr. R. H. Burt, Colonial Office (*secretary*).

Telecommunication

IN his inaugural address to the Institution of Electrical Engineers on October 7, Sir A. Stanley Angwin, president of the Institution, gave a survey of the possibilities of development of telecommunications in the international field, dealing particularly with the subject of international control and regulation and its repercussions on post-war developments in Great Britain. In dealing with international control and standardization, Sir Stanley referred to the various administrative international regulations which had come into being and to the three technical committees which studied technical questions relating to the methods of working communication channels. Reference was made to other international organizations dealing with the application of communication for a particular purpose.

The necessity for emphasis being given to the adoption of a technical basis in determining international frequency allocations leads to consideration of the three consultative technical committees referred to in the address, and the three divisions of the communications with which they deal, namely, telephony, telegraphy and radio communication. Sir Stanley dealt with the provisions to implement these services on an international basis. Reference was made to the possible developments in connexion with television, but how far these will be divided between radio and line transmission has yet to be determined. How far the employment of micro-waves for radio transmission or the new mechanism of electrical transmission by wave guides will meet the needs of television is one of the intriguing problems of the future.

New 50-Kilowatt C.B.S. International Broadcasters

AMONG the foremost short-wave radio broadcast stations in the United States are the C.B.S. International Broadcasters located on Long Island, New York, which transmit around the clock in twenty-three languages and dialects to South America, Central America, the West Indies, Mexico, Europe, Africa and Asia. Inaugurated as a part of the Columbia Broadcasting System on January 1, 1942, the new station now operates regularly with three transmitters simultaneously consisting of two 50-kW. carriers, provided by new equipment designed and manufactured by the Federal Telephone and Radio Corporation, and the 10-kW. carrier of an older unit which was moved to Long Island from Wayne, New Jersey. The transmitters operate with a total of thirteen directive arrays, using nine frequencies from 6 to 22 mc. The antenna design provides a gain of 16 decibels over a conventional half-wave antenna in free space, due to the directional characteristics, making the effective radiation equivalent to almost 2,000 kW.

The C.B.S. station is located on the 1,200-acre site of the Mackay Radio and Telegraph Company's overseas short-wave commercial radio stations on Long Island. In one case, the C.B.S. transmitters are operated on a Mackay antenna simultaneously with Mackay transmission. This is practicable since the type of antenna employed functions efficiently with more than one transmitter, provided the frequencies are separated by at least five per cent. All the C.B.S. transmitters are housed in a new, single-story wing, 40 ft. × 60 ft., with basement, added to the existing Mackay transmitter building. Three exciters and three 50 kW. final amplifiers are provided. The additional radio frequency equipment allows the operators to pre-set the frequency of one radio-frequency section while the other two radio-frequency sections are being operated simultaneously. Instantaneous change-over to the pre set frequency may then be accomplished by operating the specially designed antenna switch. The transmitting equipment is described by H. Romander (*Elec. Comm.*, 21, No. 2; 1943) in an article which deals with the station layout, radio-frequency units, radio-frequency drivers, power amplifier, antenna switching mechanism, modulators, power frequency equipment and control system. Photographs and circuit diagrams illustrate the article.

Birth-rates in Germany

ACCORDING to the *Journal of the American Medical Association* of July 31, the latest figures show a dramatic fall in the German birth-rate. In the large German cities the number of births in 1942 declined by 80,000 from 419,000 in 1940, and the rate per thousand of population fell to 13·9 compared with 17·3 in 1940. In the last quarter of 1942 the rate was as low as 12·7. The experience of the German cities is borne out by the rate for all areas of Greater Germany, which declined from 20·4 during 1939–40 to 15·2 in 1942, a loss of approximately 550,000 live births.

Comet Comas-Sola

A TELEGRAM from Lund announces that Miss Oterma has rediscovered Comet Comas-Sola very close to the position predicted by Messrs. Dinwoodie and Henderson in the "Handbook of the British Astronomical Association", 1943. Its magnitude is not indicated. An ephemeris for November is given below.

Date 1943	R.A. h. m.	Dec.	r	ρ
Nov. 4	02 16·3	+0° 55′	2·314	1·341
12	02 08·3	1 12	2·270	1·319
20	02 00·9	1 43	2·226	1·313
28	01 54·7	2 27	2·184	1·322

The Night Sky in November

FULL moon occurs on Nov. 12d. 01h. 36m. U.T., and new moon on Nov. 27d. 15h. 23m. The following conjunctions with the moon take place: Nov. 14d. 10h., Mars 5° N.; Nov. 14d. 21h., Saturn 2° N.; Nov. 19d. 21h., Jupiter 0·7° S.; Nov. 23d. 18h., Venus 3° S. The following occultations of stars brighter than magnitude 6 take place: Nov. 2d. 17h. 36·8m., 115 B.Sgr(*D*); Nov. 2d. 18h. 23·0m., 121 B.Sgr(*D*); Nov. 15d. 01h. 51·4m., 57 Ori(*R*); Nov. 18d. 01h. 50·9m., θ Cnc(*R*). The times are given for Greenwich and *D* and *R* refer to disappearance and reappearance respectively. Mercury is a morning star at the beginning of the month, rising half an hour before the sun, and is in superior conjunction on Nov. 10. At the end of the month the planet rises at 9h. and sets at 16h. 13m. Venus is a morning star, rising at 2h. 40m. at the beginning of the month, and attaining its greatest westerly elongation on Nov. 16 when it rises at 2h. 53m. At the end of the month it rises at 3h.15m. Mars, an evening star in the constellation of Taurus, sets at 11h., 10h. and 8h. 41m. at the beginning, middle and end of the month respectively. Jupiter, in the constellation of Leo, rises just before midnight at the beginning of the month, and at 23h. 08m. and 22h. 15m. at the middle and end of the month respectively. Saturn is an evening star in the constellation of Taurus. The times of setting at the beginning, middle and end of the month are 11h. 07m., 10h. 08m. and 9h. 05m. respectively. The Leonid meteor shower is due on Nov. 13–14 and the Andromedid shower on Nov. 18–25, but for some years both these showers have been very feeble and in some cases practically non-existent.

Announcements

THE thirtieth Thomas Hawksley Lecture of the Institution of Mechanical Engineers will be delivered by Prof. C. E. Inglis on November 15, at 5.30 p.m. He will speak on "Gyroscopic Principles and Applications".

THE Christmas Lectures at the Royal Institution, the hundred and fourteenth of the well-known series "adapted to a Juvenile Auditory", will be delivered by Prof. E. N. da C. Andrade, Quain professor of physics in the University of London, who will speak on "Vibrations and Waves".

LORD HORDER has been elected president of the British Association of Physical Medicine.

THE Rockefeller Foundation has made a grant of 7,500 dollars as a contribution to be used by Prof. F. F. Nord in connexion with his researches in enzyme chemistry at Fordham University, New York.

DR. L. E. C. HUGHES has been appointed head of the Experimental Department of Messrs. Rediffusion, Ltd., at their works at Wandsworth. Dr. Hughes is technical editor of "Chambers' Technical Dictionary", of which a revised edition has recently appeared.

THE Dominion Government of Canada has approved expenditure for establishing plants and equipment in Montreal and Toronto for the production of penicillin. The appropriation will cover the cost of creating the industry and that of the production of the first 20,000,000,000 units of penicillin for use by the Canadian armed forces. The new industry, employing 250 men and women, will come into operation next February.

Distribution of Nucleic Acid in the Cell

IN a recent article, Stedman and Stedman[1] claim to have discovered a new protein constituent of chromosomes, termed "chromosomin". They allege that Feulgen's reaction does not demonstrate the location of thymonucleic acid in the cell and they conclude that "the staining properties of the chromosomes towards both basic dyes and Feulgen's reagent are due to their content of chromosomin and the evidence indicating the presence in them of nucleic acid is shown to be fallacious". The argument runs as follows: Feulgen's reagent is colourized when in contact with the hydrolysis product of thymonucleic acid. The colourized product (see Baker[2]) is freely soluble in water, and it may then act as an ordinary basic stain and become attached to the acidic "chromosomin". Thus it is sufficient for thymonucleic acid to be present anywhere in the nucleus for the chromosomes to stain with Feulgen's reagent.

Although these authors do not deny that there may be small amounts of nucleic acid in the chromosomes, they lead one to infer that "there is little material left to form the nuclear sap unless this contains some nucleic acid", and indeed they suggest that the spindle at metaphase is a gel of nucleic acid.

The experiments of Mazia and Jaeger[3], however, show this position to be untenable. These workers digested salivary gland cells of Drosophila with nuclease, and then tested for products of thymonucleic acid by means of the Feulgen reaction: controls showed the chromosomes stained and the cytoplasm unstained, while the treated material showed the chromosomes unstained and the cytoplasm stained. The protein constituents of the chromosomes were nevertheless still intact in the digested cells. Nuclease-treated glands, tested by the ninhydrin reaction for protein distribution, showed the chromosomes staining more intensely than the cytoplasm. The action of nuclease is to break up thymonucleic acid, and the products of hydrolysis then become distributed through the cell: these products colourize with Feulgen's reagent, but the dye-stuff so formed does not then become differentially attached to the residual protein of the chromosomes.

The Feulgen reaction is specific for aldehydes and the pentose radicals of thymonucleic acid. Now, however, the properties of the two other constituents of nucleic acid molecules have enabled nucleic acid distribution to be examined, and the results obtained corroborate or overlap the evidence from the Feulgen reaction. The purine and pyrimidine radicals determine the characteristic absorption spectrum of nucleic acid with a well-marked maximum at 2600 A. in the ultra-violet. Caspersson[4] has shown that the chromosomes have a maximum absorption of ultra-violet light at this wave-length, at which indeed their absorption is vastly greater than that of all other cell components. When the same methods were applied to salivary gland chromosomes, Caspersson likewise showed that the bands which are stained with such nuclear dyes as carmine were also the regions of the chromosomes with a high content of nucleic acid. Moreover the contrast between the absorption by the chromosomes and by the rest of the cell (including the spindle) of light of this wave-length remains clear-cut when the protein constituents of the chromosomes have been digested by trypsin; to prove this, it was necessary, of course, that the thymonucleic acid liberated during the digestion should be precipitated by combination with lanthanum ions in the medium.

These experiments did not rule out the presence of nucleic acid derivatives in other parts of the cell. Caspersson and Schultz[5], again by means of the ultra-violet absorption technique, demonstrated concentrations of ribose nucleotides in the nucleoli and cytoplasm of egg cells and rapidly dividing tissues where the Feulgen reaction gave negative results.

The third line of independent evidence for the distribution of nucleic acid in the cell is available from the micro-incineration experiments of Barigozzi and Norberg. Barigozzi[6] showed that the dark-staining bands of the salivary gland chromosomes give concentrations of phosphorus when incinerated. This we should expect since nucleic acid contains phosphorus in every nucleotide whereas most proteins contain little or none. Norberg's[7] results, based on new photometric methods, confirm and extend those of Barigozzi.

Thus while the results of Stedman and Stedman may require that our views on the protein constituents of the chromosomes be modified, there would seem no justification for radical change in the theory of the distribution of nucleic acid in the cell and of its important relationship to various cell functions[8].

MR. CALLAN, in his defence of the established position of nucleic acid in the nucleus, has completely missed the main significance of our results. Whatever the function of nucleic acid may be, and we have no doubt that it is an important one, and however it may be distributed in the nucleus, its position as the central figure of the chromosomes has disappeared with the discovery of chromosomin. This was the point which we set out to establish in our former article, and we claim that the facts which we have adduced both there and elsewhere[1] give incontrovertible proof of our contention. In dividing cells, chromosomin is quantitatively the major constituent of the nucleus, it is concentrated wholly in the chromosomes, and its presence there supplies for the chromosome theory of heredity a basis which Mirsky[2], and no doubt many others, have recognized could not be filled by either nucleic acid or histone, the only constituents of nuclei hitherto known. We regard chromosomin, in fact, as the chemical basis of inheritance. By this we mean that the type of organism into which a zygote will develop will primarily depend upon the composition of the chromosomin contained in the gametes from which it was formed. We recognize, of course, that it must, within limits, be organized in a definite manner in the chromosomes. Variations within these permissible limits would, no doubt, account for the existence of different hereditary characters, usually ascribed to genes, within a species or race.

When we turn to the question of the distribution of nucleic acid within the nucleus we realize and admit that we are on more controversial ground. Mr. Callan has, rather uncritically, put forward data which, on the whole, constitute a considerable body of circumstantial evidence in favour of the view which he seeks to maintain. Like other evidence of this nature it is, however, susceptible to collapse when new facts emerge. Mr. Callan virtually ignores the new evidence bearing on the problem which our work has supplied.

Before considering the work of others, we must therefore make our own arguments perfectly clear. Our suggestion that the nuclear sap contains nucleic acid was made as a result of our experimental findings. From this it was a short step to the hypothesis, admittedly tentative, that the spindle was a gel of nucleic acid. Let us look at these suggestions from the cytologists' point of view. According to their present conceptions the chromosomes separate from the nuclear sap, at early prophase in the form of a thread of chromosomin. The chromosomes then contract by spiralization until metaphase is reached. Evidently the metaphase chromosomes consist of compressed cylindrical spirals, the hollow interior and the interstices between the spirals being filled with nuclear sap. If nucleic acid is present in the nuclear sap this would almost certainly combine with the basic groups of the chromosomin, thereby enhancing its power to combine with basic dyes. Such a picture, if correct, renders it difficult to decide whether to regard the central core of the chromosomes as constituting part of the chromosomes or part of the nuclear sap. It was to some extent for this reason that we were careful to admit the possibility that the chromosomes contained some nucleic acid.

What evidence have we in favour of our view ? In the first place we have shown that the presence of chromosomin in the chromosomes is sufficient to account for the staining properties of the latter. Even the results obtained with Feulgen's stain can, as we have shown, be interpreted on the same basis ; and, if any doubt still remains about this interpretation, it is completely dispelled by the results which Dr. Choudhuri, who is presenting his evidence separately, has obtained with plant cells. Without preliminary hydrolysis he has succeeded in staining the chromosomes with "developed Feulgen reagent" as effectively as when the normal Feulgen technique is employed [see NATURE, October 23, p. 475].

Secondly, in our analytical work on the composition of various nuclei, we have accounted for practically the whole of their dry weight. This analytical work has, moreover, shown that there are only three constituents (chromosomin, histone and nucleic acid) present in the nuclei in appreciable amount. Of these, chromosomin is contained wholly in the chromosomes while histone is, in some nuclei, present in insufficient amount to form the solid matter of the nuclear sap. Only one conclusion can be drawn from this result, namely, that the solid material of the nuclear sap is nucleic acid. Can Mr. Callan suggest any alternative substance to take its place ? We should add that our suggestion regarding the nature of the spindle has much to commend it. Spindle formation is an almost unvarying phenomenon in mitosis. This fact and the nature of the spindle imply that in all nuclei it is formed from an unvarying substance with the property of forming a viscous solution or gel in low concentrations. Deoxyribose nucleic acid fulfils these requirements.

The case against our suggestions is given in Mr. Callan's letter. There are a few comments which we should like to make.

(1) Mazia and Jaeger's results, contrary to Mr. Callan's opinion, support our view. They found (*a*) that the chromosomes are rapidly and completely digested by trypsin and slowly and incompletely by pepsin ; (*b*) that nuclease, while it destroyed the staining capacity of the chromosomes towards acetocarmine, did so "without affecting the integrity of the chromosomes".

(2) Caspersson had previously shown that chromosomes are rapidly digested by trypsin ; but because the effect was largely inhibited by lanthanum acetate he assumed that, in its absence, the nucleic acid was lost by diffusion. This conclusion overlooks the probability that lanthanum ions also render chromosomin completely insoluble and hence less readily susceptible to digestion.

(3) The use of ultra-violet spectroscopy for the identification of organic compounds is a purely empirical method, and has in the past led to incorrect conclusions even with pure substances. Considerable caution must therefore be exercised when applying the method to fixed or even untreated nuclei. Moreover, if one examines Caspersson's work critically one will find, as he himself admits, that the maximum absorption of the chromosomes does not correspond with the maximum of nucleic acid. From his diagrams the two appear to differ by nearly 100 A., that for the chromosomes being at about 2750 A. Is it a significant fact that this figure is almost identical with the maximum, as determined by Caspersson himself, for tryptophan ? We ask this question because, as we have previously pointed out, chromosomin is rich in tryptophan. If both the necessary chromosomin and the requisite apparatus become available to us, we shall examine this point experimentally.

(4) Norberg's work need not be considered in detail. The author himself only regards his results as preliminary ones. While we do not wish to question the sensitivity and accuracy of his actual phosphorus determinations, we do doubt his ability to separate, by the methods he employs, the chromosomes from the nuclear sap in which they are embedded.

(5) Barigozzi's results are, in our opinion, without significance with regard to the point at issue.

Effect of Thiourea on the Development of the Amphibian

IT has been shown recently that certain of the sulphonamides and thiourea act as goitrogenic agents in the rat[1,2,3]. These substances have been found also to lower the basal metabolic rate in normal animals[4,5] and to alleviate the symptoms of hyperthyroidism in humans[6,7] by inhibiting the production of thyroid hormone. Since the frog larva is one of the most sensitive indicators of the presence or absence of thyroid material, it became of interest to test the effects of such compounds on the development of the tadpole.

Rana pipiens larvæ were obtained by the method of induced ovulation[8]. Upon reaching the hindlimb bud stage they were immersed in a 0·033 per cent thiourea tap-water solution and fed a diet of boiled spinach throughout the investigation. The thiourea solutions and food were renewed daily. Definite retardation of the metamorphic process was noted so early as the second week. At the end of the third month, the hindlimbs had grown to a length of only 3–5 mm. At this time most of the untreated controls had undergone completely the process of metamorphosis. Although their differentiation was inhibited, the treated animals continued to eat and increased markedly in size and weight. The body and head showed considerable broadening; the viscera were unusually large. Their appearance corresponded to that described for the thyroidectomized tadpole[9,10]. A typical animal, following two months of treatment, measured 90 mm. in total length, 33 mm. in body-length (from snout to base of tail), and had a width (across body) of 19 mm. Its weight was 5·8 gm.; its hindlimb length, however, was only 3·0 mm. None of the several hundred untreated controls employed in this study ever attained such large dimensions.

After about a month of thiourea treatment, most of the animals developed peculiar tail abnormalities characterized by a twisting and thickening confined largely to the base. This effect could not be attributed to any peculiar environmental condition other than the thiourea, since it never occurred in any of the controls kept under similar conditions.

Several tadpoles were allowed to reach a more advanced stage in development (8–10 mm. hindlimb length), and then immersed in thiourea solutions. Here the metamorphic process continued for some time, but at a much slower rate than in the controls. This advance was due probably to the continued release of thyroid substance present in the gland prior to the initiation of experimental treatment.

That the effects of thiourea are reversible was seen from our finding that tadpoles which had been treated with this substance for two months, and then returned to ordinary tap water, promptly resumed their development and became frogs in a relatively short time.

Of especial significance is the fact that the thyroid glands of the experimental animals revealed no enlargement such as has been described in the mammal. On the contrary, the thyroids of tadpoles immersed in thiourea for two months were found to be reduced in size, contained fewer follicles and showed all typical signs of atrophy (for example, low epithelium and colloid retention). Histological studies of thyroids from animals treated for shorter periods of time and with different concentrations of the drug are now being made.

Thiourea does not operate by rendering the body tissues less sensitive to thyroid hormone since we have found that thiourea-treated tadpoles immersed in a solution of thyroxine 1 in 5 million and 0·033 per cent thiourea were transformed rapidly into frogs. Likewise, it has been shown in the mammal that administration of thyroid hormone prevents the goitrogenic action of thiourea and results in a return of the metabolic rate to normal levels[4,5]. Although the evidence is suggestive that thiourea, in the developing amphibian, acts by inhibiting the formation of normal thyroid principle, the question as to whether the drug also affects the production and release of thyrotropic hormone from the pituitary is being investigated at the present time.

Xanthine Oxidase Activity of Cow's Milk

BOOTH[1] was unable to confirm Wieland and Macrae's[2] observation that the xanthine oxidase activity of cow's milk was low when the sample was freshly drawn but underwent a spontaneous rise when it was allowed to stand in the presence of a suitable preservative. The discrepancy between the results of these workers is probably due to the fact that Booth's samples[3] had already been subjected on the farm to routine cooling, a procedure which, like shaking in air or nitrogen, is sufficient to induce a marked rise in activity[4]. By examining uncooled samples of milk, I have been able to confirm and extend Wieland and Macrae's observations. Twigg[5] kindly informs me that he also has observed the spontaneous rise in xanthine oxidase activity of samples of milk which are allowed to stand after being drawn.

The samples of milk were drawn, into sterile bottles, from Guernsey, Red Poll and Shorthorn cows over the periods December 1938 – July 1939, and March – June 1941. When cooled milk was required, the sample was divided, and one part passed over the 'cooler' within a few minutes of milking. Both uncooled and cooled samples were preserved with thymol and stored at 0–2° C.

Xanthine oxidase activity was determined by methylene blue decolorization and manometrically. In the first method, 1 ml. samples were suspended in phosphate buffer at *p*H 8·0, and allowed to react anaerobically with hypoxanthine or xanthine in the presence of $N/1,000$ methylene blue in a total volume of 5 ml. With a final substrate concentration of 0·0004 M., the activity was low when tested within a few hours of milking, but underwent a spontaneous rise up to the thirty-sixth hour. Some typical results are given in Table 1. Further slight rises were noted in samples retested on the third day, but subsequent increases were not observed, although some milks were retested up to one month after milking. Figures showing the increase in xanthine oxidase activity

P–3	10·50	78

which occurred when the samples were cooled or shaken are also given in Table 1.

The gradual rise in activity of uncooled samples occurred with varying concentrations of substrate. Thus in final concentrations of 0·0004, 0·0008, 0·0016 and 0·0032 *M*. xanthine, one sample showed activities, expressed as (reciprocal of decolorization time in seconds) × 10^4, of 22, 21, 18 and 10, respectively, when tested eight hours after milking, and of 127, 85, 78 and 72, respectively, when retested on the third day.

In the manometric estimations, the oxygen uptake of 1 ml. samples of uncooled milk, suspended in phosphate buffer at *p*H 8·0, was determined in the presence of varying concentrations of substrate. In a typical sample, the uptake per hour per mgm. of dry matter, in the presence of 0·0008, 0·0016, 0·0032 and 0·0064 *M*. xanthine, rose from 2·72, 3·28, 3·50 and 6·24 μl., respectively, when tested two hours after milking, to 5·76, 6·88, 9·20 and 9·52 μl., respectively, when retested on the third day.

Earlier studies have suggested that, in cow's milk as secreted, xanthine oxidase is in intimate relationship with the fat globules[6,7,8,9,10]. This point was further investigated by estimating the activity of samples drawn at different stages during single milkings, in which the percentage of fat increases from a low level in the 'fore milk' to a high level in the 'strippings' [11]. The initial activity, as determined by methylene blue decolorization, was found to be directly related to the concentration of fat, as shown for two typical samples in Table 2. The spontaneous rise in activity of the samples with a high concentration of fat was marked; the 'strippings' (11·1 per cent fat) from one animal had an activity (expressed as above) of only 39 when tested three hours after milking, and one of 292 when retested on the third day.

Some of the possible explanations of the spontaneous rise in activity, namely, bacterial contamination, oxygen effect, were excluded by the experiments of Wieland and Macrae. Release of activity accompanies aggregation of the milk fat globules[4], and hence coincides with disruption of their surface membrane, a structure which appears to be composed of a complex of phospholipids and a membrane protein, different from other known milk proteins[12,8]. It seems possible that the protein bearer of xanthine oxidase forms part of this membrane, and is secreted in the spread condition, in which it might well be inactive.

Tarassuk and Richardson[13] have recently reported that the lipase activity of freshly drawn milk undergoes a marked rise when the sample is cooled to between 15° and 20° C., and it would be interesting to follow the activity on 'cooling' or standing of other milk enzymes.

I am indebted to Dr. T. F. Macrae for suggesting this work, and to Drs. V. H. Booth, Harriette Chick, J. F. Danielli and M. Dixon for their criticisms. At the time this work was carried out, I was Ministry of Agriculture and Fisheries student in animal health.

Intracellular Symbionts of Insects as a Source of Vitamins

IN our previous communication on the vitamins of the B group required by insects[1], we pointed out that the difference in the vitamin requirements of two groups of beetles, one comprising Tribolium and Ptinus, and the other Lasioderma, Sitodrepa and Silvanus, was possibly due to the presence, in the latter group, of intracellular symbionts. Tribolium, Ptinus and (unpublished) the moth *Ephestia elutella* require thiamin, riboflavin, nicotinic acid, pyridoxine and pantothenic acid, and, to a lesser degree, choline chloride and biotin as essential growth factors. Lasioderma, Sitodrepa and Silvanus grow successfully in the absence of some of these vitamins, although their requirements differ in detail. The growth of normal larvæ of *Lasioderma serricorne* and *Sitodrepa panicea* and of *Ptinus tectus* on diets containing all the chemically known factors of the vitamin B complex in pure substance (whole diet) and on diets which were lacking in one single B factor are shown in the accompanying table.

In continuation of these experiments, Lasioderma and Sitodrepa have been obtained free from symbionts by surface sterilization of the eggs (according to Koch[2]), and the vitamin requirements of the normal and the sterilized larva have been compared. It is seen in the accompanying table that the vitamin requirements of sterilized larvæ are very different from those of the normal larvæ, and in every respect resemble those of Ptinus. Sterilized larvæ of Sitodrepa grew as well as unsterilized larvæ in the presence of all the vitamins, or in the absence of either *i*-inositol or *p*-aminobenzoic acid. This indicates that sterilizing had no harmful effect provided the diet remained optimal. No growth of sterilized larvæ took place in the absence of the five important factors of the B complex, thiamin, riboflavin, nicotinic acid, pyridoxine and pantothenic acid, and little growth in the

	Lasioderma unsterilized	Lasioderma sterilized	Sitodrepa unsterilized	Sitodrepa sterilized	Ptinus
Whole diet	++++	+++	++++	++++	++++
No thiamin (B_1)	++	—	—	—	±
No riboflavin	++++	—	++(+)	—	—
No nicotinic acid	++++	—	++++	—	—
No pyridoxine (B_6)	++++	—	+++	—	+
No pantothenic acid	+++	—	++	—	±
No choline chloride	++	—	+++	+	++
No *i*-inositol	++++	+++	++++	++++	+++
No *p*-aminobenzoic acid	++++	+++	++++	++++	+++(+)

Efficiency of the whole diet is indicated by ++++. The whole diet consists of casein 50, glucose 50, cholesterol 1, insoluble part of yeast 5, McCollum's salt mixture 2, water 15 parts; wheat germ oil 7 mgm./gm.; thiamin, riboflavin, nicotinic acid, pyridoxine, pantothenic acid and *p*-aminobenzoic acid (50 μ gm./gm. of the dry diet); choline chloride and inositol (500 μ gm./gm.).

absence of choline, while the normal larvæ grew quite well in the absence of any of these vitamins (except thiamin). The results obtained with Lasioderma are similar, the only difference being that sterilized larvæ, in the presence of all the vitamins, or in the absence of inositol or *p*-aminobenzoic acid, grew slightly more slowly than normal ones.

It had been suggested before[2,3] that the role of intracellular symbionts in insects might be to provide accessory food substances, but this is the first experimental evidence in support of that suggestion which has yet been brought forward. Full details of this investigation will be published elsewhere.

We gratefully acknowledge a Government grant of the Royal Society, which, partly, made this work possible.

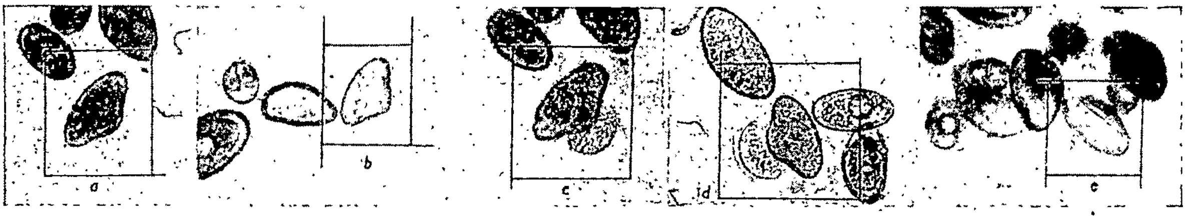
Germination of the Sporangia of Coelomomyces Keilin

ONE of us (J. M.) has found several fungal infections in mosquito larvæ in Northern Rhodesia. The sporangia appear similar or related to those described by Keilin[1], Iyengar[2] and Walker[3], and we tentatively relegate them to the genus Coelomomyces K. So far as we know, no previous worker has observed the germination of sporangia of the genus Coelomomyces, though Keilin appears to have had a shrewd guess as to what was likely to happen.

The sporangia, all thick-walled, which we succeeded in getting to germinate were found in a larva of a species of Mucidus (Dipt. Culicidæ). The process of germination is well shown by the accompanying photographs. A sporangium when about to germinate first loses its oil droplets and the interior becomes granular. (*a*) A slight bulge appears on one side; (*b*) the bulge enlarges, the outer hard shell ruptures and the thin internal membranes appear; (*c*) two thin membranes are now visible, and the contents of the sporangium flows out and is confined within the inner of the thin membranes; (*d*) the two thin membranes are now easily visible and are more widely separated. This, unfortunately, was the last photograph of the actual germination that could be taken. The next, and by far the most spectacular phase, was the sudden coming to life of the zoospores. Up to stage (*d*), no separate zoospores could be seen because of the close packing in the sporangium; with the extrusion of the inner membranes, however, the pressure is released and the spores come to life. Once having started to move around they gradually gain speed until the interior of the sporangium and the extruded thin membranes are a seething mass of zoospores. In a few minutes after the beginning of movement, the zoospores contained within the extruded membrane find their way out to the exterior and immediately swim out of the field of observation. More zoospores from inside the sporangium take their place, and gradually the whole empties itself and all that is left is a sporangium with a rent through which the thin membranes had extruded (*e*).

The time taken to reach the stage shown in (*c*) may be a day or two. Once the zoospores flow into the extruded thin membranes, complete liberation takes place in a few minutes. During the act of leaving the sporangium one does not gain the impression that the extruded membranes suddenly burst, because they appear to remain intact, and zoospores leave gradually as if they were capable of penetrating the thin membranes without rupturing them. The zoospores have a single flagellum. The body measures about 4 μ, and the length of the flagellum is approximately four times this length. They progress head first and the flagellum is not undulated but whipped rather stiffly from side to side.



We are indebted to Dr. S. Selby of Johannesburg for the loan of his microphotographic apparatus, which made it possible for us to make a large number of exposures with the minimum delay.

Stereomorphism in Cryptic Coloration of Lepidoptera

Cryptic effect, that is, the inconspicuousness of the organism in its natural environment, depends upon three main causes: (1) the coloration of the cryptic organism should resemble that of the surroundings; (2) the body-shape is often modified to resemble environmental components (stick insects, etc.); (3) the effect is that of a quiescent organism and not of a moving one, and the attitude of rest and the bodily components are exactly adapted to each other. According to Oudemans' rule[1], the cryptic colours of resting Lepidoptera are the only visible ones, while all the bright telechromatic[2] areas are concealed. The above three groups of factors form a definite system independent in a way of other bodily systems and using the body, as it were, as a sort of substratum irrespective of its organs. The term 'cryptom' may be given to the system.

According to Thayer's principle of counter shading[3], the orderly distribution of colours is largely responsible for the effectiveness of the cryptom, the main result of the working of the principle being that the convex bodies, for example, of birds, are rendered visually flat. The cryptoms of Lepidoptera, and especially Rhopalocera, are mainly located on th wings. Because the latter are flat, Thayer's principl is not applicable to them. Using stereoscopic apparatus and the method of stereomodels, I was able t show[4] that cryptoms of this sort are governe by the principle of stereomorphism[5], that is, that o cryptic wings two-dimensional images are present so that the relation of the flat cryptom to som hypothetical microlandscape corresponds to that o a photograph of a landscape and the landscape itself On these stereomodels the pattern components ar imitated by shadows cast by their sculptured non coloured surface (see illustration). The relief of th latter may be very complicated according to th cryptom copied, and consists of a number of raise and lowered areas which are generally curved an often pass into one another by gentle alterations o their directions and inclinations.

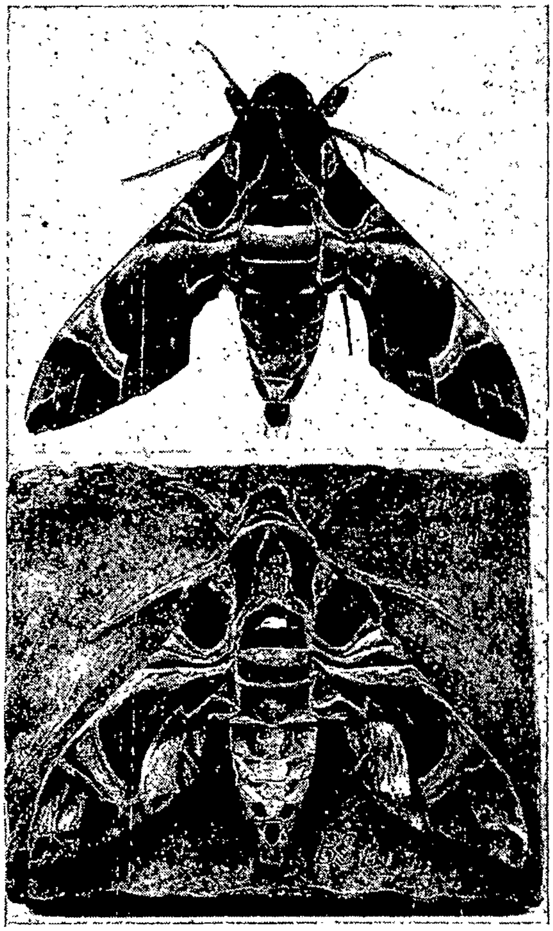

Fig. 1. (Above): A specimen of the hawk moth, *Daphnis nerii* L. (Below): A clay monochrome model of the above moth in which the colour pattern is imitated by the distribution of shadows on the sculptured surface of the model. The method proves that the colour pattern of the moth represents a two-dimensional reproduction of hypothetical three-dimensional bodies. Due to this, the cryptic effect of this sort of coloration is very strong.

But in Cott's excellent book[6] the above model are described as consisting of "different surface lying in the same plane but on different levels", an it is argued that the surfaces in question should b regarded as sloped and curved. My paper is illustrate by the model of *Erebia lappona* chosen as a ver simple example of the method and consisting as matter of fact of flat surfaces. But in the text, "protuberances and depressions of different shape an size" seen through stereoscopic devices are spoke of, and mention is made of the model of *Daphni nerii* illustrated in the accompanying figure. Thi model consists of a number of variously sloped surfaces, many of them being curved. It was exhibite at a scientific meeting in 1939 and the photograp published in 1941[5]. The basic idea of the researc in question is "that the wings of moths and butterflies imitate bark, leaves and the like"[4]. Because th typical surfaces of objects of this sort are curved the surfaces of models could not be restricted to fla shapes. The latter should be regarded as a particula example of a surface normally curved. Thus Dr Cott's interpretation of my models and my own view are at variance.

Binucleate Oidia on Binucleate Myceliun of *Polystictus hirsutus* Fr.

Brodie[1] remarked that the occurrence of binucleate oidia on binucleate mycelium of basidiomycetous fungi is rare. The only example cited s far seems that of *Pholiota aurivella* Batsch by Vandendries and Martens[2].

While carrying on pairing experiments with closel related species of Polypores on agar films on slides I came across an oidial strain of *Polystictus hirsutu* which is heterothallic and bipolar[3]. This was paire with *Polystictus steinheilianus* Berk. and Lev. (a non oidial one). Binucleate oidia in four or five shor chains arising direct from binucleate hyphæ of *P* *hirsutus* with clamp-connexions were obtained clos to the line of demarcation between polysporou cultures of the two closely related species, and ther was a number of hyphal fusions between hyphæ of *P. hirsutus* and *P. steinheilianus* at the line of demarcation. Farther away from the line, monocaryon oidia in short chains like the fingers of the human hand were found due to haploidization of the binucleate hyphæ of *P. hirsutus*, no clamp-connexions having occurred on the oidial hyphæ. In single (polysporous) culture of *P. hirsutus*, only monocaryon oidia were obtained, as noticed by Brodie in dicaryon mycelium of *Collybia velutipes*. So the presence of binucleate oidia in this case may be ascribed to the influence of pairing of *P. steinheilianus* on *P. hirsutus*.

For the observation of nuclei in oidia the agar-films were fixed in Allen's bouin and stained with Haidenhain's iron-alum hæmatoxylin. Dicaryon oidia were cylindrical while monocaryon oidia were oval.

A Case of Club-Root of Swedes Due to a Seed-borne Infection

CLUB-ROOT caused by *Plasmodiophera brassicæ* Wor. is one of the most serious diseases to which cultivated Brassicas are subject. The disease usually results from the planting of susceptible crops in contaminated soil, and the general assumption is that the infection is contracted from the soil. So far as I am aware, the relevant literature contains no record of an outbreak of the disease traceable to the use of contaminated seed. Three outbreaks of the disease which occurred in 1942 and 1943 in a Manchester garden could not, however, be traced as being due to a soil contamination. A survey of all attendant circumstances showed no previous Plasmodiophera history in the immediate locality or contributory circumstance by which it could have been introduced into the garden, and the evidence pointed to a seed-borne infection.

As a small quantity of seed which had given rise to a diseased swede crop was available, experiments were carried out, designed to show, if possible, whether or not the disease had been seed-borne. If, in fact, the seed was infected, then a surface contamination with infected soil resulting from contact of the fruit with soil either before or during harvest was suspected, and the experiments were made with this possibility in mind. All sowings were made in boxes of compost and all the compost components and the containers were effectively sterilized. Fertilizers were added to the mixture as recommended for John Innes compost but no lime was added.

For each variety, one box was sown with untreated seed and one with seed 'surface sterilized' with hypochlorite. As controls, two boxes of Cambridge No. 5 Brussels sprouts were used. The Brussels sprouts seed had previously given disease-free plants. Two further boxes of Brussels sprouts were sown and immediately after sowing watered with swede seed washings obtained by soaking the swede seed in distilled water over-night.

Seed was sown on July 22. Germination was good in all boxes, and the seedlings grew satisfactorily. By mid-September some of the swedes had developed swellings at the bases of the hypocotyls and typical clubbed roots; in the cells of which numerous plasmodia of *P. brassica* were present. All the plants were harvested and minutely examined on October 1, and the data obtained are assembled below:

	Total number of plants	Per cent infected
Swede, var. Best-of-all		
Untreated seed	40	52·5
Surface sterilized seed	46	41·3
Brussels sprout with Best-of-all swede seed washings	27	0
Swede, var. Conqueror		
Untreated seed	45	15·6
Surface sterilized seed	63	1·6
Brussels sprout with Conqueror swede seed washings	30	16·7
Brussels sprout		
Untreated seed (1)	42	0
Untreated seed (2)	63	0

The small amount of seed available precluded the carrying out of any more elaborate experiments, but the results obtained point clearly to the disease in the swedes being seed-borne. Further, the results obtained are entirely explicable if there is surface contamination of the seed; and surface sterilization of the seed with hypochlorite is no more, or not much more, effective in removing this than washing with water alone. Whereas the contamination of the Conqueror swedes is easily removable, that of the Best-of-all swedes is more adherent, with the result that while Conqueror seed washings cause infection of Brussels sprouts, the Best-of-all seed washings fail to do so. The conclusion that the disease is seed-borne and in one case at least (and probably in both) due to surface contamination appears inescapable.

Having established that club-root may appear in brassicas because of a seed-borne infection, some points of considerable importance are raised.

To determine what proportion of new outbreaks of the disease is in fact due to this cause is well-nigh impossible as so rarely is suspected seed available for experimental purposes. Nevertheless, even if the proportion is small and the risk of introducing the club-root organism into clean ground by this method remote, the development of suitable methods of seed sterilization may be worth while, while the importance of growing brassica seed crops only on clean land is clearly indicated.

I am indebted to Dr. H. J. Western for confirming my identification of *P. brassica*.

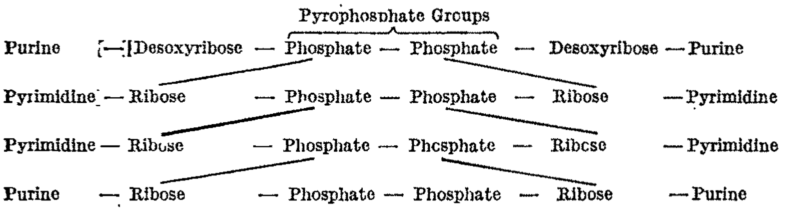
A Speculation on the Nature of the Chemical Structure which is the Essence of the Malignant Cell

ALTHOUGH it must be presumed that the chemical constitution of the cancer cell diverges in some subtle yet profound manner from the non-malignant, up to the present definite suggestions as to the manner of this difference have not been formulated in terms of atoms and molecules. Thus evidence for abnormal respiratory exchange has been adduced by many investigators and rebutted by other workers; the secret of malignancy has been attributed to chromosome abnormalities, to gene mutation, lack of hormone balance, irregularity of enzyme constitution, etc.

The concept submitted below is possibly little more than an integration of current ideas, but it is set forth because this simple chemical aspect has stimulated us to what we believe to be intelligently planned if, thus far, unfruitful experiments. It may occasion useful criticism and clarification by others who can bring to bear upon it diverse aspects of knowledge.

The essence of the idea is the formulation of a molecule in the chromosome capable of splitting into two similar symmetrical portions. Visualization of the severance of this molecule during division of the chromosome gives a picture of the vital process of reconstitution of this most important nuclear material in each 'daughter' cell. Further, in the case of the malignant cell, the molecule is to be conceived as impelled on a course of irreversible division. In the chromosome itself, no doubt associated with other nuclear constituents, there would be a vast marshalling of such molecules in the cleavage plane. The specific molecule envisaged is a nucleic acid linked through pyrophosphoric acid to nucleotide groups.



Pyrophosphate Groups
Purine — Desoxyribose — Phosphate — Phosphate — Desoxyribose — Purine
Pyrimidine — Ribose — Phosphate — Phosphate — Ribose — Pyrimidine
Pyrimidine — Ribose — Phosphate — Phosphate — Ribose — Pyrimidine
Purine — Ribose — Phosphate — Phosphate — Ribose — Purine

There is much evidence that compound nucleotides, some of them exhibiting this pyrophosphoric group, are of great importance in cellular processes, for example, co-dehydrogenase I, thiamine pyrophosphate (co-carboxylase), riboflavine-adenine dinucleotide, and phosphagen, while the active principle of embryonic extract which promotes growth of cultured tissue, and possibly the milk factor of inherited mammary cancer in mice, may possess this structure. Consideration of the behaviour of viruses, which have attributes of a living organism and of a pure chemical, gives support to such an idea. It has been suggested that when such an entity multiplies, it does so by laying down a copy of itself on a 'template' system.

We suggest, then, that in the 'resting' phase, that is, when engaged in ordinary cellular activities, the cell has, as its essential basis, molecules of nucleic acid joined by pyrophosphoric linkings to nucleotides similar to those mentioned above which subserve its normal metabolic activity. When cell division is about to take place the metabolic nucleotides on one side of the linkage are replaced by, or are converted into, nucleotides which are the mirror image of those on the primary nucleic acid portion. The symmetrical, double nucleic acid then splits, with resultant division of the chromosomes accompanied by the associated phenomena which comprise 'cell division'.

In the case of the malignant cell, however, we would postulate that because of the abnormal juxtaposition of specific side chains, or the presence of abnormal linkings in such groups, the symmetrical development of the dual nucleic-acid molecule proceeds directly and continually instead of via the usual attachment of the metabolic type of nucleotide groups.

The factors determining the abnormal production of nuclear material might, therefore, be various, that is to say, any of the agencies which we term carcinogenic; for example, the effects occasioned by the chemical or physico-chemical attachment of the well-known carcinogenic chemicals or their reaction products, by radioactive elements, X-rays or light waves, or more directly by a virus which in itself is a compound tetra-nucleotide which undergoes division with little 'metabolic' activity.

On this hypothesis the rapidity with which a virus may induce tumours in certain organisms compared with the slow influence of pure chemicals and hormones would be explicable, while the apparent anti-cancer influence ascribed to some vitamins of the B complex and also the role of co-carcinogens could be interpreted in terms of chemical structure. The disappearance or alteration of normal cell function in many cases could also be inferred, while the occurrence of simple tumours and various grades of malignancy can all be comprehended as governed by such a mechanism operating through the pyrophosphoric di-nucleic acid structure.

Recently Stedman and Stedman[1] have described a protein component of cell nuclei present in much greater proportion than nucleic acid, but the discovery does not necessarily overthrow the belief that nucleic acid is the master constituent. The chromosomin moiety may play a most important part in providing the requisite environment for the elaboration of the 'double' nucleic acid.

Flinders Petrie's Racial Types

IN 1887, the British Association published the report of a committee which had enabled the late Sir Flinders Petrie to photograph and make casts of a large series of 'Racial Types' from Egyptian wall-reliefs and frescoes. A limited edition of prints was published and has become very rare. In the report of the committee it was stated that the negatives were deposited with Mr. Browning Hogg, 75 High Street, Bromley, Kent, who would supply prints. It has been ascertained that Mr. Hogg ceased to live in Bromley after 1888; but the Association has no record concerning the negatives subsequent to 1887. It is now desired to trace them if by any means possible, since a number of these 'Racial Types either are not included in Max Burchardt's series (c. 1913) or are much better photographs, and no later work of this nature has been done. The Association will be grateful for any information.

RESEARCH ITEMS

The Naivasha Fossil Skull and Skeleton

These interesting remains were excavated by Dr. L. S. B. and Mrs. Leakey in July and August 1940 from a very rich prehistoric site at the base of a cliff a few miles from Naivasha (*J. E. Africa Nat. Hist. Soc.*, 16, 169; June 1942). Most of the skeleton was *in situ*. A large number of artefacts, mainly obsidian implements and fragments of implements, was found in the same silts. This associated industry somewhat resembles that known as Upper Kenya Aurignacian Phase "C", but may prove to be a slightly later date, as yet unnamed. The relationship of this Naivasha skull and skeleton to other East African prehistoric skulls is not at all easy to determine. Leakey's conclusion is that it probably resembles a male of *Homo sapiens* type, and is dated as belonging to the closing phase of the Gamblian Pluvial, after the second maximum of that Pluvial had passed. The skull is long and very narrow, with the very low cranial index of 64·52. The type represented has no very close affinity to any other prehistoric types from Kenya, though it bears a certain resemblance to the Oldoway skull from Tanganyika Territory, which is also attributed to the closing stages of the Gamblian Pluvial and is probably connected with a late stage of the Upper Kenya Aurignacian culture.

Density of Certain Marine Organisms

Interesting data that throw light on the relationship between certain marine organisms and their environment and mode of development are reported by A. G. Lowndes (*Proc. Zool. Soc.*, Ser. A, **113**, 28; 1943). In decapod Crustacea the resting ovaries have a density approximating to that of protoplasm (1·0565) but the ova have a much higher density (1·1129 for *Maia squinado*), and the early embryos are so dense (1·1170) that they would be unable to swim and to lead an independent life. They possess an appreciable store of food and are carried by the females; they become free-swimming only when their density has fallen. In the copepods, when the zygotes are extruded there is a great increase in volume due to water absorption and a corresponding decrease in density, so that embryos of low density and capable of an independent existence result. The data for the Echinodermata are fewer, but they show that in four species, as the ova develop, their density decreases, so that the early embryos have such a low density that they can be supported in the water by their own cilia, and this obviates the necessity of a large food store in the ova and of carriage by the females, and permits the early assumption of a free-living habit.

Fishes from the Phœnix and Samoan Islands

Leonard P. Schultz reports on a large number of fishes from these islands, collected in 1939 during the Navy Survey Expedition of the U.S.S. *Bushnell*, to which he was attached as naturalist (U.S. Nat. Mus. *Bull.* 180, 1943). This unique opportunity for securing rare and interesting material resulted in the capture of an enormous number of fishes, upwards of 14,000 being collected, with about 3,000 specimens of other groups. Thirty new fishes belonging to six new genera are described and many new records are given. There are useful keys to species, and, in some cases, to genera and families; and the report is illustrated by diagrams, figures and plates. Valuable colour notes are included, taken at the time of collection. Among the larger fishes the order Apodes is well represented, the genera belonging to six families, seven species being new. Of the smaller fishes there are many gobies, including thirty-four genera. The report is purely systematic and no notes relating to the natural history of the different fishes are given.

Interspecific Translocation of a Chromosome Arm

A. Håkansson (*Hereditas*, 29, 141; 1943) has examined the progeny of a hybrid between *Godetia Whitneyi* and *G. deflexa* created by Hiorth. By repeated back-crosses a red-nerved plant with fifteen chromosomes was obtained which produced a large deficiency of red-nerved plants in its offspring on crossing to normal fourteen-chromosome *G. Whitneyi*. The extra chromosome presumably carrying *R* for red-nerves was eliminated during meiosis. By X-raying such red-nerved plants Hiorth found a plant which segregated fifty-five red-nerved to sixty-four normal plants, that is, almost equality. Håkansson found that this plant has fourteen chromosomes and forms bivalents regularly, but that one pair of bivalents was heteromorphic. There is no sign of pairing of the longer arm of one member of this bivalent and it presumably was derived from *G. deflexa*, whereas the rest of the chromosomes were derived from *G. Whitneyi*.

Silver Compounds as Fungicides

The toxic action of silver compounds for certain fungi has been known for a considerable time, but the high cost of silver and the awe of its being a precious metal doubtless inhibited any extensive exploitation of its fungicidal properties. Lowell W. Nielsen, however, has made extensive tests of silver compounds as the toxic agents for spray fluids (Memoir 248, Cornell Univ. Agr. Exp. Sta., Ithaca, N.Y.; November 1942). The trials were all made in an inoculation chamber, using the potato and *Phytophthora infestans* as the host and parasite respectively. Several silver compounds and mixtures gave promising results, the best being a combination of silver nitrate, ferrous sulphate and lime in the approximate proportions 15 : 25 : 15, and diluted with water to a strength of 100 p.p.m. of silver. This mixture had also satisfactory adhering qualities. The experiments are part of the search for a spray fluid which would be less harmful to certain kinds of foliage than those commonly used. They establish the most useful mixture, but do not yet include field trials, or any economic evaluation, though the estimated cost for materials of about one cent per gallon of spray fluid does not appear excessive.

Chemical Evolution of the Ocean

E. J. Conway has discussed in illuminating detail the principles governing the composition of ocean water and its variation during geological time (*Proc. Roy. Irish Acad.*, 48, B, 9; 1943). The main hypothesis is based on the assumption that the ocean volume has remained essentially constant, with additions of chlorine either from the original atmosphere or from volcanic sources. A subsidiary hypothesis based on the idea of a growing ocean fed by juvenile water is more briefly treated. It is shown that the removal of potassium from the ocean by living organisms, with subsequent conversion to glauconite, has played a major part in the chemical evolution. A noteworthy effect which may be correlated with the large-scale appearance of fossils in Cambrian time was to bring about a marked increase in the concentrations of calcium and magnesium ions and a corresponding decrease in the sulphate concentration. The oceanic composition of the early Ordovician period—about the time of the first appearance of vertebrates—is compared with the composition of mammalian blood plasma. The oceanic salinity was then about three times that of such plasma and had a different composition pattern, particularly with respect to calcium and magnesium. It is pointed out that the apparent discrepancy between the age of the ocean as measured by chemical denudation and that of the oldest rocks dated by radioactive methods tends to disappear when account is taken (*a*) of sodium deriving from rock silicates alone, and (*b*) of present-day factors which lead to abnormally high rates of denudation. The paper is highly original in methods and fruitful in results, and deserves careful study by all who are interested in the geochemical history of the oceans.

Erratics of the Cambridge Greensand

IT is well known that the Cambridge Greensand has yielded a great variety of erratic pebbles and boulders. L. Hawkes has made a careful study of the collection of 163 erratics housed in the Sedgwick Museum, Cambridge (*Quart. J. Geol. Soc.*, 93–104; 1943). About forty different types of sedimentary, igneous and metamorphic rocks have been recognized. Two boulders may be matched with the paisanite of Mynydd Mawr, North Wales; others with the Uriconian rocks of the Midlands and Welsh borders; but the majority, two of which are of types unknown in the British Isles, cannot be localized. The boulders were floated to the Cambridge region, probably in the roots of trees, during the period of formation of the Greensand deposit. They prove that land existed at this time in North Wales and adjoining areas, probably as a peneplain of Lower Palæozoic and Pre-Cambrian rocks diversified with monadnocks such as Mynydd Mawr. The prevailing currents appear to have been from the west, and it is surmised that nearly all the erratics could have been derived from land in this direction, with Northern Ireland as a probable source for the schists and gneisses of the collection.

Sub-Crustal Structure of New Zealand

THE structure of the earth's crust immediately beneath New Zealand has recently been investigated by R. C. Hayes ("The Subcrustal Structure in the New Zealand Region from Seismic Data", by R. C. Hayes, *Bull. Seismological Soc. Amer.*, 33, No. 2, April 1943). The author states that it has become evident from recent investigations that there is some definite arrangement in the distribution of earthquake origins in the New Zealand region. Earthquakes originate below normal depth in many parts of the region, depths of several hundred kilometres occurring beneath the volcanic zone in North Island. Depths of focus have been plotted. The results seem to show the existence of a discontinuity of more or less regular form, its depth varying from about 30 km. in some places to a maximum of more than 350 km. It is suggested that the material below this discontinuity is so viscous as to have been distorted by plastic flow into folds, the most marked one having its crest along the east coast of North Island from near East Cape to south of Cook Strait. Its slope appears to be very steep toward the north-west. Above the discontinuity earthquakes occur, and recent major shocks at various points near the crest of the fold suggest that it continues to be forced upward, causing fracture and fault-slipping in the more brittle material above.

Synthesis of Succinic Acid

A NEW synthesis of succinic acid $(-CH_2COOH)_2$ is reported by M. S. Kharasch and M. T. Gladstone (*J. Amer. Chem. Soc.*, 65, 15; 1943), in which acetyl peroxide dissolved in glacial acetic acid is dropped slowly into glacial acetic acid maintained at 95°–100°. A mixture of methane and carbon dioxide is evolved. The acetic acid was removed by distillation in vacuum and the residue when crystallized from water gave succinic acid. With *iso*butyric acid, tetramethylsuccinic acid was obtained, and with chloracetic acid, *meso*-dichlorosuccinic acid. It is supposed that a free radical mechanism is involved:

$$(CH_3CO)_2O_2 = CH_2\cdot + CH_3COO\cdot + CO_2$$
$$CH_3COOH + CH\cdot = \text{complex} = CH_4 + \cdot CH_2COOH$$
$$2\cdot CH_2COOH = (-CH_2COOH)_2.$$

Flow of Viscous Fluids

ABOUT the problems of fluid flow which commonly arise in engineering practice a large amount of information has been collected by experimental methods. In six notes (A. Fathy, S. Bishara, S. A. M. Hassanein, Physical Department Paper No. 44, Government Press, Cairo, 1943) the theoretical aspect of these problems is approached by methods which differ from those usually adopted both in respect of the mathematical statement and of the empirical simplifying assumptions. The notes comprise: analysis of motion in natural co-ordinates (stream-lines and their orthogonal trajectories); critical state of flow (particularly in channels); non-uniform flow in open channels; frictional conditions and velocity distribution in turbulent flow; flow through circular pipes; breakdown of the laminar state of flow.

Photovisual Magnitudes of Double Stars

A. W. J. COUSINS has a paper with the above title (*Mon. Not. Roy. Astro Soc.*, 103, 3; 1943) which describes the measurement at Durban Observatory of photovisual magnitudes for 119 stars in the southern hemisphere. Fabry's method, which was used very successfully by the late E. G. Williams and H. Knox-Shaw, at the Radcliffe Observatory, Pretoria, to determine the magnitudes and colours of *O*- and early *B*-type stars south of −35° declination, was adopted, but in the present case stars of all spectral types are included. A full description of the apparatus which was used is given, and there are tables showing the results obtained. The standards used for the determination of the zero point were the photovisual magnitudes of eight of the brighter stars of the Pleiades, which Calder obtained in 1937. When reduced to the Harvard photovisual system it was found that there existed differences of scale and zero point and also a large colour coefficient. After applying certain corrections for atmospheric extinction (a serious source of error in employing Fabry's method for this class of work), the mean deviation between the two series is ± 0·09 m. On comparing the results with 11 *B*-type stars which were also observed by Williams, the mean deviation was found to be only ± 0·025 mag.

CULTURE AND MANUAL SKILL

By C. W. HANSEL

A CRITICAL analysis of the traditional classical education in Britain reveals in many of its rotagonists a narrow and prejudiced outlook, almost pride in ignorance of science, and a contempt or manual skill. They seek to apply to the social roblems of to-day a strangely perverted form of hat they regard as the best ideas and practices of reek times. Their choice and adaptation have been nfortunate, because much that is worthy of imitation as not been followed, and a great deal of inferior ubstitution has been made. Traditional classical ducation lies nearer to scholasticism than Hellenism. t is unbalanced in its blindness for everything except ook learning, and it is dangerously inadequate in hat it ignores the many and only partially caters or the few. Further, it is apparently unaware of he complete transformation of civilization which has esulted from the progress of science, industry, and he arts.

Sir Richard Gregory has said, "There has always een a lag between stages of scientific knowledge nd social or moral wisdom. What is particularly eeded to-day is to promote public interest in the lose relationships of natural science with other umanistic studies which influence the thoughts and ctions of all citizens."

The education of the Greek, at the time of Plato, onsisted, up to the age of about seventeen, of very imple instruction in the three *R*'s, music, and dancing r gymnasium. Then followed a period of compulsory ublic service from seventeen to twenty. If worthy f further education, from twenty to thirty he studied athematics and science, but not to the neglect of ublic duty. Philosophy was reserved for later life. here is much that is attractive in this system. here is no forcing of the pace, but a natural growth f the mind. There is an insistence on national ervice from everyone. There is recognition of educaion as a life-long process, schooling being merely art of it. Education is cultural not vocational, the ne object of leisure. There is the exclusion of abstract nd philosophical discussion from the education of hose lacking maturity and experience. There is an mmense and just appreciation of the mother tongue. nly two matters call for criticism: the undue mphasis on memory and the veneration of warlike ursuits: "Pallas I celebrate, sacker of cities, terrible oddess of war" (Aristophanes).

How has Greek education been modified in the raditional classical education of Britain? Every esirable feature of the Greek system has been hanged or eliminated and almost every undesirable ature of scholasticism has been retained. The chool retains the seclusion of the monastery; it is sually unconnected with home life and with the ommunity in which the pupil will afterwards live is life. Far too much is attempted for the mind f the young pupil to expand naturally, with the esult that the English language and literature are eglected in the attempt to cover excessive detail a multiplicity of subjects by sheer memorization nd imposed instruction instead of naturally acquired nowledge through the medium of concrete experience and self-instruction.

One of the most serious defects of classical instrucion is the contempt it breeds for manual skill. his is one of the legacies of Greece and Rome. Archimedes is not mentioned in the twelve volumes of Grote's "History of Greece" or the eight volumes of Thirlwall. Quoting from the Langhorne translation of Plutarch's "Lives": "Eudoxus and Archytas who gave a variety and an agreeable turn to geometry, and confirmed certain problems by sensible experiments and the use of instruments, which could not be demonstrated in the way of theorem. . . . But when Plato inveighed against them, with great indignation, as corrupting and debasing the excellence of geometry, by making her descend from incorporeal and intellectual corporeal and sensible things and obliging her to make use of matter, which requires much manual labour, and is the object of servile trades; then *mechanics* were separated from geometry, and being a long time despised by the philosopher, were considered as a branch of the military art." "Archimedes . . . considered all attention to *mechanics*, and every art that ministers to common uses, as mean and sordid, and placed his whole delight in those intellectual speculations, which, without any relation to the necessities of life, have an intrinsic excellence arising from truth and demonstration only."

Quoting from a Royal Institution lecture by Prof. Benjamin Farrington: " 'What are called the mechanical arts', says Socrates, 'carry a social stigma and are rightly dishonoured in our cities.' " "The word surgery is, of course, simply the modern form of the Greek cheirourgia, which means manual operation. And we shall find reason for connecting the decline of anatomy after Galen with the ancient prejudice against the cheirourgos, the surgeon or manual operator." "That the Greeks early acquired a contempt for manual labour is certain. 'The noble are those who have escaped the yoke of manual labour' (Herodotus)." " 'The sick in our cities', writes Plato in the *Laws*, 'are of two classes, the slaves and the free.' " "Theirs were the crafts which Aristotle defined as being necessary for the existence of the city but as disqualifying their practitioners from citizenship."

The denial of culture to the craftsman is surely born out of an entirely unbalanced education and a completely mistaken and narrow view of culture. Culture proceeds from all those activities of mind and body that are worthy of cultivation. Matthew Arnold once said "culture unites classes"; this can scarcely refer to a state of mind which fails to recognize the dignity and worth of labour and manual skill.

Sir Richard Livingstone in "Education for a World Adrift" (see NATURE, May 8, 1943) speaks of "spiritual values" and the "noble ideals of Hellenism". The "Age of Science" he identifies with an "Age without Standards". He finds in Greek literature (even in translations) a "philosophy of life" not to be found elsewhere. Does he prefer the inhuman recital of strife, intrigue, and cruelty, for example, in Plutarch's "Lives" to what youth may learn from Smiles' "Lives of the Engineers"? Does he prefer to dwell on "the torture of the boat" rather than on the work of Lister or Pasteur? He asserts that science is non-moral and unconnected with standards of value. Has he read the second Huxley Lecture of the Anthropological Institute, by Francis Galton (see NATURE, Oct. 29, 1901)?

Sir Benjamin Brodie, in an address to the Royal Society (1859), said: "Physical investigation, more than anything besides, helps to teach us the actual value and right use of the Imagination—of that wondrous faculty, which, left to ramble uncontrolled, leads us astray into a wilderness of perplexities and errors, a land of mists and shadows; but which, properly controlled by experience and reflection, becomes the noblest attribute of man; the source of poetic genius, the instrument of discovery in Science, without the aid of which Newton would never have invented fluxions, nor Davy decomposed the earths or the alkalies, nor would Columbus have found another continent."

Only one defect of classical instruction has been discussed. There are several others. The philosophical speculations of traditional Hellenism and the mechanical memorizing and formalism of medieval scholasticism have dominated educational schemes for centuries. Such a system of instruction has been tried and found wanting—it has masqueraded under the name of education. Let our educational aims be more worthy and appreciative of our glorious English literature, more adapted to human needs, and a study of Christian rather than pagan principles. The English language and literature, together with the arts and sciences (including mathematics) and the cultivation of a sound body, provide the basis of a complete and balanced education and a generous culture.

RHEOLOGY IN THE TEXTILE, LEATHER, SHOE AND ALLIED TRADES

AT a meeting of the British Rheologists' Club, held at Loughborough College on September 18, papers were read by Mr. A. Pollard, Dr. C. A. Maunder Foster, Mr. A. March, Mr. P. Danby and Mr. P. Stanley Briggs, and there was a discussion under the general title of "Rheology in the Textile, Leather, Shoe, and Allied Trades". It is convenient to deal with the proceedings in sections.

Textiles

In weaving, two banks of multiple warp threads are opened ('shedding'), a shuttle holding a single weft thread is passed through the 'shed' ('picking'), and a comb-like reed forces the weft into place ('beating'). The next 'shedding' operation locks the weft into place. Small inaccuracies in these three locating operations are, with staple material, partially corrected by the hairy projections from the yarn. With a smooth yarn such as rayon, which is solid rather than tubular, better location is needed; and the low 'tenacity' of the material calls for less alteration of stress than occurs in the normal 'broadcloth' loom.

In one modern ribbon loom, attention was given to these matters; warp tension was kept constant (the healds moving over the arc of a circle, centred at the line of the weft), the beating reed was given a very low amplitude, and all moving parts of the machine were very exactly controlled. Besides giving accurate and reproducible weaves, the output-rate of this machine is of the order of 1,000 'picks' per minute, or some 4–5 times normal speed of production.

A poor view was taken at the meeting of the engineering ability of many designers and builders of textile machinery in general. One assertion was made, that 'tenacity' of yarn (breaking strain in ounces per denier) does not necessarily measure its probable behaviour in weaving.

Shoemaking

Great use is made of stitching: upper construction; joining of lining to upper, of upper to insole of insole to welt, and of welt to outsole. Each o these operations is alike in outline; but as each uni process of the stitching differs according to th particular job, a whole range of machine designs, o awls, needles, shuttle threads, and of sewing threads is required.

For lubricant, the hand cobbler uses beeswax shuttle threads are waxed; sewing threads are rosined; and the material which, in the making operation, acts as lubricant, after cooling down seals the holes and preserves the threads.

In toe, and in heel, reinforcement is used. For this purpose the toe 'puff' may be shoddy cloth, sized with pitch or pyroxylin; or, for miners' boots, it may be steel. The toe-cap, puff reinforcement and lining must suffer the drafting strains of pulling on to a rigid wooden last; and thereafter must retain shape, and hold together as a unit.

The stiffener for the heel part is required to be rigid at its meridian, thin and flexible at its top edge.

After the shoe has been lasted, there is a hollow space under the middle of the insole; this mus be suitably filled with a composition having resilience before the outsole can be sewn or stuck on. Thus the foundation of the average shoe is a 'sandwich' of leather insole, cork composition or felt filler, and leather or rubber outsole. Should the filler be too soft, it will shift under the pressure of the foot, to give lumps and hollows in the insole surface which will be uncomfortable in wear.

Resilience, deformability, flexibility and the like are most often judged by the test of the trained finger-and-thumb. It would be desirable to have an artificial digital assembly, not subject to fatigue (or to prejudice), for these purposes.

In the operation of shoe-building, rubbery adhesives are largely used. The processes are repetitive mechanical, and output is very large (the standard figure for the United Kingdom is rather less than 100 million pairs annually).

The adhesive maker needs, therefore, to maintain a steady consistency in his products; and this task is not simple with some of the present-day materials For example, with a falling sphere viscometer, a thick paste of reclaim rubber solution may appea to have both thixotropic and dilatant properties. In a case such as this, trials were made, using a rotation viscometer, to obtain a consistent reading, so tha a method might be available for works use. Rotation times were taken with different loads, after various periods of stirring. Constant time for a single turn was attained in a typical experiment on a Störme instrument, after sixteen turns. Provided the load was above a certain lower limit (2 kgm.):

Load 2·1 kgm. after	1	2	4	8	16	32	turns
Time of single turn (sec.)	36	26	21	16	10	10	

Restoration of the system to the former high viscosity figure could not be completed: after 100 hours it was still slowly increasing, in linea fashion.

For measurements on this kind of stuff, the torsional viscometer was recommended as more suitable

Leather Finishes

The last treatment of leather, prior to sending to the warehouse, is to apply pigmented and dyed dressings or colourless seasons to the front surface (which is normally the grain side, but sometimes is the flesh side). The finishes used for this effect should have properties approximately the same as the surface layers of the leather to which they are bonded.

Some 50 per cent of the leather substance is animal protein in nature; the rest being added material of diverse origin. Animal protein likewise forms the main basis of leather finishes; with wax, shellac, pigment, grease and sulphated oil as the other ingredients, all dispersed in water.

So that the behaviour of the finishing materials under strains of the sort to which leather is subject might be studied, isolated films were stressed to the break-point. These films, between 10 μ and 15 μ thick, were cast on a rubber substratum, conditioned some days at 70 per cent relative humidity, and test pieces cut and stretched at a steady rate. Typical figures were:

	Casein	Shellac	Casein 4 : Shellac 1	Casein 4 : Wax 1	Casein 9 : Pigment 1
Elongation % at break	75	65	125	75	75

Casein plasticized with sulphated oil

	1%	2%	4%	8%
Elongation % at break	230	250	310	350

The optimum figure was got with 6 per cent plasticizer.

Several other forms of behaviour of leather finishes have to be controlled; partly in the formulation, and partly in the mode of application and after-treatment. These properties include gloss, hardness, colour, flexibility and 'feel'.

One of those present doubted the applicability of test results on continuous films; when the same material after application to the leather forms a largely discontinuous film. It was also asserted that pigment particle average size (say, 2 μ) is unimportant; the deciding (adverse) factor being the proportion and size of the larger aggregates of pigment. These, giving rise to marked localization of subsequent strains, might cause low adhesion and a brittle finish.

Leather Making

In the course of the conversion of raw animal hide into leather—soaking, liming, bating, tanning and so on—the aim is to control the closeness or openness of texture ('angle of weave'), the breakdown of reticular tissue, and the splitting (into 'fibrils') of the fibre-bundles.

Picturing the structure of leather as a trellis-work (in three rather than two dimensions), a closely-knit trellis, with high 'angle of weave', would be seen to present a compact collection of fibre-ends at the boundaries of the material. This was desirable where abrasion resistance is needed, as in sole-leather; and such a system is not readily deformable, and has elastic rebound. Close texture, coupled with considerable fibre splitting, would yield a somewhat more deformable material, as for example shoe upper leather.

In sole leather, the tannage is not pushed very far, and much filling material ('non-tans') incorporated; the grease content being small. In upper leather, the combined tan is higher, with less filler, and the texture internally lubricated with much grease. A tabular comparison is as follows:

	Sole leather	Upper leather	Belting leather
Angle of weave	high	high	low
Fibre splitting	slight	marked	marked
Tan %	18	24	24
Non-tan %	33	7	14
Grease %	3·5	17	11·5

These data related to vegetable tannage.

The chemical processes of the tannery, and the sundry mechanical treatments, can be so controlled that only one factor remains out of the tanner's reach. Until the animal can be so bred and reared as to produce a standardized pelt, this last factor would most likely continue to be an independent variable.

C. A. Maunder Foster.

MARINE BIOLOGICAL RESEARCH IN SOUTH AFRICA

The first of a series of pamphlets to be published by the Research Survey Committee of the Association of Scientific Workers of Southern Africa has recently appeared*. The work of the Committee is "intended to help in stimulating and developing research in the Union and in affording constructive suggestions for building up a more adequate and satisfactory organisation of research within the country". Dr. Wm. Edwyn Isaac, the writer of the present pamphlet, is on the staff of the Government Low Temperature Research Laboratory, where he has lately been working on problems of food technology and on South African seaweeds as sources of agar. He directs attention to the acute need in South Africa for basic research on marine problems and to the extreme shortage of laboratories and staff, giving excellent summaries under various headings: the fundamental cycle of life in the sea, knowledge of plankton basic to the fisheries, a brief history of fisheries research in the Union, our knowledge of chemistry and physics and of the marine biology of South African seas, certain general considerations arising out of the review of fisheries and marine biological investigations in South Africa, and, finally, a project for a marine research institute with special reference to plankton.

Marine products are among the least exploited of the Union's resources, although the fauna is a vastly rich one and there is abundance of fish. In 1934 the Board of Trade reported that the annual consumption of fish in the Union is only 4½ lb. per head of the population, and, later, C. von Bonde and Rees Davis directed attention (1942) to the small fish consumption. The corresponding values for Britain and Norway are 41 lb. and 70 lb. respectively. A sound knowledge of the marine biology and hydrology of the regions concerned is imperative, and at present only the fringe of such studies has been approached.

The project for a research institute with special reference to plankton is a good one, including as it does suggestions for special work at first conducted from one central research institution, later spreading to several marine stations with their full number of boats. It is urged that such a marine research institute should be concerned only with fundamental research, and although keeping in close touch with the fisheries should be freed from the routine of fisheries work. Although the desirability of a marine research institution is discussed more particularly in relation to plankton work, the author states that it is obvious that it would concern itself with all the fundamental aspects of marine biology. Work on the life-histories of the most important fishes is clearly one of fundamental significance, and it is to be hoped that it would occupy a large place in the planning of the work in the marine institute.

---

* Marine Biological Research and the South African Fishing Industry. By Wm. Edwyn Isaac. Research Memorandum I, 1943. Published for the Association of Scientific Workers of Southern Africa (Cape Town Branch) by the African Bookman, P.O. Box 3115, Cape Town. 1*s.* 6*d.*

Sites for the central laboratory and for three substations are suggested. All these plans should not be too difficult to carry out in the near future, and although admittedly a background of fundamental knowledge can only be acquired by long years of patient work, the sooner this is begun the better. With such an unexplored field it is hopefully maintained that results of practical significance might emerge soon.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, October 30

Royal Anthropological Institute (at the Royal Society, Burlington House, Piccadilly, London, W.1).—Centenary Meeting.

At 11.15 a.m.—Sir John L. Myres: "A Century of Our Work".

At 3 p.m. (at 21 Bedford Square, London, W.C.1).—"The Future of Anthropology". (Dr. G. M. Morant: Physical Anthropology; Prof. V. G. Childe: Archæology: Mr. R. U. Sayce: Material Culture; Dr. R. Firth: Social Anthropology).

Monday, November 1

British Social Hygiene Council (in the Hastings Hall, B.M.A. House, Tavistock Square, London, W.C.1), at 3.30 p.m.—Sir Walter Langdon-Brown: "Social Biology and Planning".

Royal Institute of Chemistry (Yorkshire Section) (joint meeting with the Leeds University Chemical Society) (in the Chemistry Lecture Theatre, The University, Leeds), at 6.30 p.m.—Dr. A. D. Mitchell: "Demonstration of Improved Methods in Volumetric Analysis".

Tuesday, November 2

Society of Chemical Industry (Plastics Group) (joint meeting with the Institute of Plastics Industry and the Institution of Rubber Industry) (at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2), at 2 p.m.—Symposium on "Rubber-like Plastics and their Applications".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Henry Dale, G.B.E., P.R.S.: "Progress in the Treatment of Infections", 1: "Assisting Nature's Reactions".*

Sheffield Metallurgical Association (at 198 West Street, Sheffield 1), at 6.30 p.m.—Discussion on "Hardenability" (to be opened by Mr. T. F. Russell, Dr. R. J. Sarjant and Dr. W. Steven).

Wednesday, November 3

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Dr. E. F. Armstrong, F.R.S.: "The Long Road of Progress".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 3 p.m.—Scientific Papers.

Institution of Electrical Engineers (Wireless Section) (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. J. Kemp: "Wave Guides in Electrical Communication".

Thursday, November 4

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir James Jeans, O.M., F.R.S.: "The Methods of Modern Astronomy", 1: "Spectroscopic Astronomy".*

Association of Austrian Engineers, Chemists and Scientific Workers in Great Britain (joint meeting with the Association of Austrian Doctors) (at Austria House, 28 Bryanston Square, London, W.1), at 7.15 p.m.—Dr. F. Scholl: "Chemotherapie im lichte neuer Forschungen—Sulphonamide und Penicillin".

Friday, November 5

National Smoke Abatement Society (at Caxton Hall, Westminster, London, S.W.1), at 10 a.m.—Conference on "Measures for the Prevention of Smoke in relation to Plans for Post-War Reconstruction".

Society of Chemical Industry (Yorkshire Section) (at the Queen's Hotel, Leeds), at 3.30 p.m.—Dr. Wm. Cullen: The First Brotherton Memorial Lecture.

Physical Society (in the Physics Department of the Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 4.30 p.m.—Dr. Bruce Chalmers: "The Non-destructive Testing of Metallic Components."

Royal Institution (at 21 Albemarle Street, London, W.1), at 5 p.m.—Dr. A. O. Rankine, F.R.S.: "The Dispersal of Fog".

Saturday, November 6

Nutrition Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1).—Conference on "Post-War Nutritional Relief".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Mechanical Engineering—The Principal, Technica College, Brunswick Road, Gloucester (November 4).

Borough Electrical Engineer and Manager—The Town Clerk Town Hall, Leigh, Lancs. (endorsed 'Borough Electrical Engineer and Manager') (November 4).

Cultivations Officer to the Isle of Wight War Agricultura Executive Committee—The Executive Officer, Lugley House Lugley Street, Newport, Isle of Wight (November 6).

Specialist Teacher for the Remedial Treatment of Stammering—The Director of Education, Education Offices, Burnley (November 6).

Teacher of Mechanical Engineering Subjects—The Principal, Luton Technical College, Park Square, Luton (November 9).

Borough Engineer and Surveyor and Water Engineer—The Town Clerk, Town Clerk's Office, Brook House, Dover (endorsed 'Borough Surveyor') (November 15).

Head of the Electrical Engineering Department—The Secretary, Robert Gordon's Technical College, Aberdeen (November 20).

Forest Engineer, and an Assistant Forest Engineer (must be good mechanical engineers with experience in sawmilling, steam engines and mechanical logging operations), for the Sierra Leone Forestry Department—The Secretary, Overseas Manpower Committee (Reference No. 1114), Ministry of Labour and National Service Alexandra House, Kingsway, London, W.C.2.

Teacher of Mathematics and Mechanics—The Principal, Erith Technical College and Day Technical School, Belvedere, Kent.

Mechanical and Electrical Engineers (2) with (a) ability to stimulate and supervise local production in ferro-alloys, carbide detinning, electrodes, etc., and be familiar with metallurgical work, and (b) conversant with foundry and metal work and construction—The Ministry of Labour and National Service, Central (Technical and Scientific) Register, Alexandra House, Kingsway, London, W.C.2 (quoting Reference No. C.1910A).

First Assistant Engineer (Reference No. E.776), and a Second Assistant Engineer (Reference No. E.777)—The Ministry of Labour and National Service, Central (Technical and Scientific) Register Alexandra House, Kingsway, London, W.C.2 (quoting the appropriate Reference No.).

EDUCATIONAL RECONSTRUCTION (5)

Compulsory Part-time Education

THE Government's White Paper on Educational Reconstruction is headed by a, well-known quotation : "Upon the education of the people of this country the fate of this country depends". That, of course, is profoundly true. It states the broad problem of the future in undeniable fashion. But it has been also significantly underlined by the Prime Minister when he said : "The future of the world is to the highly educated races who alone can handle the scientific apparatus necessary for pre-eminence in peace or survival in war". Implicit in that statement is the need to know what *kind* of education we are to provide for those who are to follow us.

The White Paper is necessarily concerned with the machinery rather than the content of education. But the structure of the machinery is obviously not without its indications of content possibilities, since it at least shows us something of the scope of education which the machinery will permit.

Consider the proposals for compulsory part-time education, since the main criticism of our present full-time education arrangements is directed at this aspect. Full-time education ceases about the age of fourteen. What does that mean to us if we are really considering education as something upon which the fate of Great Britain—and that means the fate of the children of this country—depends ? Sir Richard Livingstone has summed up its meaning in one vivid phrase : "To cease to be educated at 14 is as unnatural as to die at 14". But in case the phrase be open to any quibble at all, let us use an equally vivid and descriptive phrase which occurs in the White Paper itself. If the effects of education carried on only to the age of fourteen are thin and liable to wear off quickly in the rough and tumble of the industrial and commercial world, the language of photography provides us with the reason. "The process of education for the vast majority of children", says the White Paper, "offers at present an example of 'under-exposure, under-development and insufficient fixing'."

Something has to be done then to remedy the defect, and the first step is to raise the school leaving age to fifteen and, later, to sixteen. But even that is not enough. The full value of raising the school leaving age will not be secured unless the results are consolidated. How is that consolidation to be secured ? There must, says the White Paper, be continued supervision of the health of young people after full-time schooling has ceased, and opportunity must be provided to develop their capacities and interests. The present War very quickly showed us that if the provisions for day continuation schools in the Education Act of 1918 had been operated, many of our present problems would not have arisen.

The White Paper therefore makes it clear that "all young persons from 15 to 18 will be required to attend an appropriate centre part-time, unless they are in full-time attendance at School or otherwise under suitable part-time instruction". The attendance will be taken from hours of employment and, at first at any rate, will be limited to a day per week or its equivalent. Moreover, we are glad to note that the old title of 'day continuation school' is to be abandoned, and 'young people's colleges' substituted. That, indeed, is not the best title, but it is better than a title which might indicate that what is to be done is a mere extension of previous schooling. The point to be emphasized is that a new phase of life and development is to begin.

We need not enter here into details of variations of a general plan which may have to be made. The rural areas present problems which will have to be resolved. So also do the cases of young persons serving at sea. But these matters are noted and recognized by the White Paper and will, we hope, be brought within the scope of the new proposals without excessive difficulty.

Already we have pointed out that the proposals for this new machinery give indications of the scope and content upon which interest and thought must be concentrated. The indications are clear so far as the young people's colleges are concerned. The young people concerned will be engaged in a variety of occupations. For all of them, however, there are basic elements which must be included in their training. Thus "provision must be made for their well-being through physical training and remedial exercises and instruction in health and hygiene. The school medical service will be extended to cover them. . . . Other essential elements will be training in clarity of expression and in the understanding of the written and the spoken word, together with some education in the broad meaning of citizenship to give some understanding of the working of government and the responsibilities of citizens and some interest in the affairs of the world around them".

If that be achieved, we believe a prime move will have been made to produce people who can "handle the scientific apparatus necessary for pre-eminence in peace or survival in war".

Technical, Commercial and Art Education

We turn now to the proposals for "Technical, Commercial and Art Education", and here we note one of the two major issues to which the White Paper directs attention: the need for the further development of these branches of education.

That need has been heavily underlined by the War. We know now how vital a contribution has been made to the war effort by the technical colleges. They have, to put the matter quite mildly, not only trained munition workers and members of the Forces; they have also worked miracles as production centres. The White Paper recognizes their contribution. They have "made a contribution to the specialized training of the personnel . . . the value of which cannot be over-rated . . . they have shown, notwithstanding the handicaps imposed by war conditions, that they can assist in effective training to a degree and in a way, the possibilities of which industry has not hitherto generally appreciated". Vast developmen in industry and commerce are now envisaged, an we have in these columns already indicated the nee which will exist for special training. It is well, ther fore, to note that the White Paper suggests tha "industry and commerce should review their arrang ments for training, and should co-operate in ass ciating the technical colleges and art schools mor fully with the industrial and commercial life of th country".

Our present system—and the White Paper inte polates the remark "if it can be called a system" will clearly be insufficient and inadequate to the cal the future will make. We note, for example, tha at present the provision of further education is power and not a duty of the local education authoriti and technical education has not advanced in conce with the needs of a highly industrialized communit We note, too, that "in particular the standards the buildings and equipment in use have often bee deplorably low, and comparison with what can seen in other countries which have been our co petitors in the world markets, can leave little cau for satisfaction". In pre-war days a programme f the provision of colleges and the expansion a bringing up to date where necessary of others alrea in existence had been made, and for that purpo capital expenditure of some £12,000,000 was co templated.

The White Paper indicates that this is to remedied. The cost will be considerable. That recognized: "The post-war cost of such a programm will inevitably be higher [than the £12,000,000], b it will be of the first importance that these pla should be revised and expanded to meet the ne requirements, and, as soon as possible, carried in effect". With that in mind provision will be made place a duty on education authorities to provi adequate facilities for technical, commercial, and a education, both full-time and part-time.

So far, so good. In general the White Paper's pr posals must be regarded as satisfactory up to th point. But it is here we must turn to the append to the White Paper which deals with the financi implications of all the proposals. We are warn that "it is not proposed to introduce any of t proposals until after the war". Thereafter there is plan which will occupy some four years, and "t development of technical and adult education is n included among the matters to be dealt with in t first four year plan". Nevertheless "some allowan has been made for preliminary expenditure in resp of technical education".

How much? The allowance for "preliminary e penditure" is to be made two years after the Wh Paper scheme begins to operate, and it will form o 1·11 per cent of the total educational expenditu In the succeeding years this percentage falls to 0 per cent, and then, in successive years, beco 0·58, 1·21, 2·45 and 2·98 per cent. Thus, seven ye after reconstruction has begun, less than 3 per ce of educational expenditure is concerned with te nical education.

The Parliamentary Secretary to the Board ducation, in a recent debate, said that the figures present the capital charges on new buildings. We onder what new buildings are to be secured for an xpenditure of these dimensions. And, in the meanme, what is to happen about the equipment which so early must be provided ? What estimates are enisaged to secure the greatly increased recruitment f the highly qualified and experienced teaching staff hich will be necessary ?

We can provide no answers to these questions. We cord, as of course anyone must record if the need r educational reconstruction be clearly known and ppreciated, our admiration of the broad sweep and aracter of the proposals which the White Paper as adumbrated. But we cannot help expressing the ar that, if so much time must elapse after the War efore the real and concrete work of educational construction can begin, there will be a very clear anger that the high hopes the educational proposals ave raised may very easily be disappointed. We not pretend to ignore the difficulties. Of course ere will be difficulties. No one knows when the ar will end. There will be many things to be done hen it does end ; things which will be called priorities d which indeed will be noble and inescapable iorities. But when we talk of technical education e believe we talk of something which is inextricably nked with the welfare and success of that vital dustry and commerce upon which will rest the ssibilities of so many of the social improvements e country expects. There must then be no lapse time in reforming our present system so that it ay meet the demands which will be thrust upon it.

We hope, then, that the Government will review time-table of educational reconstruction and give vift and real meaning to the proposals we have ted and long to see put into effect.

THE FUTURE OF TECHNICAL COLLEGES

HE correspondence which has been proceeding in the columns of NATURE under the heading he Future of Technical Colleges" is both timely d important. Recent publications, such as the hite Paper on Educational Reconstruction, and e still more recent report of the Parliamentary d Scientific Committee on "Universities and Rearch", show a growing awareness of the fact that Great Britain is not to be overwhelmed by the ing tide of science, it will be necessary to mobilize the scientific and technical ability the country n muster. We shall need all the pure scientists can discover, a far greater number of first-class chnologists, and an innumerable host of skilled chnicians. In the education and training of this my of reconstruction, both the universities and the chnical colleges must play a part, and the task is, ite frankly, beyond their present resources. Before blic money is spent, as it must be, on increasing ose resources, it is clearly desirable, in the interests economy of both money and man-power, that the respective functions of the universities and the technical colleges shall be clearly defined, and each of them equipped for their appropriate functions.

It is unfortunate that a single rather emphatically worded sentence in Dr. Lowery's letter in NATURE of August 21 should have been construed as an attack on the quality of the instruction given in the technical colleges of Great Britain, since the volume and vigour of the quite natural reaction has rather swept the discussion from its most fruitful channels, and has caused the many admirable suggestions made in that letter to fall somewhat into the background. No one would question that, in days when universities were few and university scholarships both hard to come by and inadequate in amount, technical colleges performed a valuable service by stepping into the breach, and enabling men of high ability, who through lack of funds were unable to obtain the university education which their talents would have justified, to establish themselves in the scientific world by means of an external degree. The system whereby such men should have to depend for their education on the classes available in the local technical colleges, often after the end of a full day's toil, cannot be regarded as more than a temporary expedient. It no longer satisfies either the social conscience or the urgent needs of the times. As the White Paper states, "high ability should not be handicapped by accidents of place of residence or lack of means in securing a University education". Courses in technical colleges, however efficient the instruction and equipment, do not constitute a university education ; nor can the matter be entirely rectified by affixing the stamp of an external degree to the product. The fact that in some of the larger cities of Great Britain a university and a technical college may be found flourishing side by side, shows that the two types of education are not felt to be identical (City Fathers are not usually guilty of extravagance in matters of education) and that in a complete educational system each is needed to supplement the other.

It is important that this duality of function should not be overlooked in planning the reorganization and extension of higher education. It is an expression of a similar duality in human interests : on one hand, the desire to understand; on the other, the desire to construct. Each is essential to human progress. Each requires its appropriate type of training. The primary function of a university is the conservation and extension of learning, and the training of men and women who shall carry on this tradition. Every university department is, or ought to be, a research department, and it is for this reason, rather than for any supposed superiority in equipment or standard of teaching, that it is important that students whose interests and aptitudes mark them out as the research workers of the future should receive their education within a university.

From a utilitarian point of view—there are, of course, others—the importance of such students lies in the fact that the science of to-day becomes the industry of to-morrow. Relative to the large number of technicians and technologists who will be required to staff our industries, their numbers will probably always be small. As Sir Lawrence Bragg has pointed out, the output of first-class physicists, for example, is only about one per annum per million of the population. Our survival as a great industrial nation may well depend on doubling our production of university graduates in pure and applied science.

For the training of the great army of technicians which modern industry demands, we must look, not to the universities but to the parallel branch of education which is represented at present mainly by the technical colleges, and for two reasons. In the first place, many capable technically minded students find the wide range and strict mental discipline of a university course both difficult and distasteful. In the second place, the power of a university to fulfil its own special function in the community depends on an equal and harmonious development of all its faculties. A wholly disproportionate growth of the technological faculties would so seriously impair the fabric that the institution would almost cease to function as a university at all.

The arguments which have led the Norwood Committee to recommend the division of secondary education into academic (grammar school) and technical apply with equal force in the sphere of higher education. As the students from the grammar schools look to the universities for their further education, there should be technical colleges of similar status to which the student from the technical secondary schools can look for further training. Few of the existing technical colleges of Great Britain, handicapped as they are by the necessity of providing an immense number of courses for students of the most elementary type, can be said adequately to satisfy these requirements. What is needed, as Messrs. Barber and Andrews have already urged in their letter in NATURE of October 2, is the development and adequate endowment of a sufficient number of institutes of technology, corresponding to the Technische Hochschulen of the Continental system, capable of playing the part in technical education which the universities fulfil in pure and applied science and the humanities. Such institutions would need no stamp from an external university to guarantee their students. Their existence would give a new status to technical education as a whole.

The relations between these new colleges, the local technical colleges and the applied science departments of the universities, clearly call for much thought and mutual consultation, if wasteful overlapping of functions is to be avoided. So also, as has already been pointed out in the leading article in NATURE of October 16, does the method of apportioning the students to the most appropriate institution. The Board of Education, as guardian of the technical colleges, might well initiate such consultations. The Government is being pressed, and rightly so, for large capital grants both for university and for technical education. It is important that their relative functions shall be wisely decided before the money is spent. The opportunity of obtaining an adequate and well-balanced system suited to the needs of the times will not soon recur.

TECHNIQUE OF BLOOD GROUPING

Blood Grouping Technic

A Manual for Clinicians, Serologists, Anthropologist and Students of Legal and Military Medicine. B Dr. Fritz Schiff and Prof. William C. Boyd. Pp. xiv 248. (New York: Interscience Publishers, Inc. London: Imperia Book Co. Ltd., 1942.) 5 dollar

DR. BOYD in the preface to this book state "Some years ago Dr. Schiff approached n with the proposal to assist him in getting out a up-to-date book on blood grouping technic, somewh on the lines of his well-known book in German (Die Technik der Blutgruppenuntersuchung)". A English version of this Continental classic, r vised and brought up to date, would always b welcome.

The translation of the senior author's script l Dr. Boyd has been masterly. With its concise, cle and straightforward sentences, this book is a mod of modern English style. The title describes it as manual for clinicians, serologists and anthropologist who will welcome it for the wealth of its content Students and tyros in serology will likewise welcon the book for the clarity of the presentation of th material.

Chapters 1 and 2 on the theoretical foundatio and general technique of blood group determinati give a brief but comprehensive survey of the subjec The methods considered in Great Britain to be th most reliable are strongly recommended by th authors, who at all times stress rightly the need f adequate controls to all group determination. Th *A*,*B*,*O*, *M*,*N*, and *P* factors are all well and fully dea with. The *Rh* factor is described briefly and the light of modern knowledge rather inadequatel (This is accountable for by the fact that the bo was published in 1942 and therefore probably writt in 1941.) Only the earliest work of Landsteiner a Wiener and of Levine, Katzin, Vogel and Burnha is quoted.

Chapter 3 describes the application of blo grouping techniques. First, there is the applicati to blood transfusion. Careful grouping of bo donor and recipient and equally careful cros matching are constantly stressed. The choice of donor—friend, volunteer or professional—is discusse and the regulations governing blood donors and blo banks in New York City are quoted. The secti on blood and plasma banks might well have be omitted or alternatively elaborated.

Secondly, the problems of relationship, includi disputed paternity, are discussed *in extenso*. Th authors insist that, although the principle of th procedures can be understood by all, the actual tes should be entrusted only to experts. An expert defined as a person, with adequate scientific trainin such as is symbolized by the degree of Ph.D., Sc.I M.D., or equivalents, who for a number of yea has been carrying out blood grouping tests and co ducting research in serology as applied to blo groups, and the emphasis is placed on the resear worker rather than the routine hæmatologist as th expert of choice.

Thirdly, other forensic applications are co sidered. The identification of blood stains is al regarded as a procedure only to be undertaken l those with experience in the techniques involve These are fully described. The methods of testi gans, secretions, and body fluids other than blood, e also noted.

Fourthly, an account of the related factors, includ g the Forssman antigen, in animals is given.

Finally, blood group investigations in anthropology e described. "Blood group determinations are aracteristics genetically determined, by a known echanism, absolutely objective in character, abso tely unaffected by environment, not subject to utation at any rapid rate, and, so far as we are able discover by extensive investigation, non-adaptive. it is possible to discover anything about the course human evolution by classifying mankind, the most eful data should be the blood groups". This titude of the author (or authors) is the keynote an interesting section. Once again a reliable chnique and a careful evaluation of results are nphasized. Methods of examining archæological aterial, mummified tissues and bones, are also ven.

Forty-five figures and sixty-seven tables are cluded in the book. On the whole they clearly ustrate the text, though in a few instances diagrams e presented with little accompanying explanation, hich may be confusing to the uninitiated.

The number of references to the literature, it is aimed, has been reduced to a minimum, but the imber will be adequate for most readers.

JOHN F. LOUTIT.

FOREIGN TRADE AND TARIFFS

ade Regulations and Commercial Policy of the United Kingdom

y the Research Staff of the National Institute of conomic and Social Research. (National Institute of conomic and Social Research, Economic and Social udies No. 3.) Pp. x+275. (Cambridge: At the niversity Press, 1943.) 15*s.* net.

THIS book is a portion of the British contribution to a study of international trade regulations and mmercial policy which was initiated at Geneva in 38, and which was designed to give a comprehensive cture of the major changes in the methods of control world trade since the conclusion of the War of 14–18. The outbreak of the present War has terfered with the completion of the project as iginally conceived; but it has been thought sirable to publish the descriptive material now, aving certain statistical studies and consideration the economic issues along with an examination of e changing international economic position of the nited Kingdom for discussion in a later volume. is was undoubtedly a wise decision; for in the esent work we have, as the chairman of the Council Management of the National Institute of Economic d Social Research remarks in his preface, a tech cal descriptive study which provides a convenient d more detailed picture than has hitherto been ailable of the development of British commercial licy, and particularly of Protectionism in all its rms, up to the end of 1938.

What has happened since then will cause more ofound changes in Britain's future economic posi n in the world than even the booms and slumps and cks and experiments of the 1930's. This is well t for future study.

It is not to be expected that a work of this kind, onsored by a committee and finally revised by one its members, would be much more than an objective and an accurate account of Acts of Parliament, commercial treaties, statutory rules and orders and the like. Even if it were only this, a very great debt of gratitude would be due to the National Institute for getting so much into so convenient a compass. But the book is something more than a catalogue, and the reader who wishes, to take one example, to study the course of Imperial Preference, will find much to help him in addition to the mere enumeration of negotiations embarked on and agreements concluded. It is, however, strictly limited in scope and its plan requires it to omit an account of the background prior to 1914 against which its contents have always to be pictured.

Many of the difficulties in trade encountered in the 1930's can be traced to origins back in the free trade period just after the middle of the nineteenth century. It was then that the Dominions imposed tariffs and began to build up infant industries which drove out home products from the Colonial markets. Soon, they claimed complete economic autonomy, and after the War of 1914–18 they assumed, in due course, all the powers of independent States. At Ottawa in 1932 they succeeded in inducing the United Kingdom to adopt a policy of tariff exclusiveness and thus laid the foundations of what was hoped would become an imperial economic unity. In all this they took the initiative, and the measures they advocated were directed primarily to secure their own economic interests rather than those of the mother country. Perhaps, as events have turned out, this was not altogether a bad thing. But the present War will leave them (certainly some but, possibly, not all) still stronger as against the United Kingdom than they were in 1938. Dominion status, in consequence, may require a new Statute of Westminster to deal with a greatly altered situation, and considerations other than economic ones will probably assume major importance in the settlement that will then ensue.

But these changes in the mutual economic relations between the component parts of the British Empire were part of a development which was widespread throughout the world. A period in which raw materials and semi-finished goods of foreign origin were imported and worked up to be exported as finished goods to other countries was being superseded by a period characterized by the exchange of manufactured goods for manufactured goods, in which the international movement of raw materials tends to fall and every country to work up its own resources. British politicians and economists were slow in recognizing this trend, and one of the latter could write in 1914 that so far as he could foresee "a large interchange between countries of foodstuffs and raw materials against manufactured goods is destined to continue for an indefinite time to come". The War of 1914–18 stimulated the movement, and in 1925 the Balfour Committee on Industry and Trade was able to diagnose the situation correctly in its "Survey of Overseas Markets". By 1938, taking Japan, Canada and Italy as examples of industrially young countries creating their own national industries, the volume of the international trade of these countries with one another and the rest of the world was much below that of 1929. This is true, also, of other countries industrially older, and particularly of Russia. Indeed, it was the industrialization of Russia, depriving Germany of raw materials and of a market for the sale of finished products, which caused Hitler, as many passages in "Mein Kampf" testify, to look to that country as a source of supply at any cost for Germany of materials not found in sufficient quantities at home—materials to be obtained by force when trading methods failed.

That the United Kingdom experienced similar difficulties is demonstrated by the detailed story of tariff-making as set out in the volume before us. What lessons can planners and reconstructors learn from this ? Are they to assume that the tide will continue to flow in the direction it took in the 1900's and maintained so strongly in the 1930's ? If so, then they ought to aim at what is called a 'balanced' agriculture, at production of high-quality goods by skilled craftsmen, at the development of small-scale rural industries, at wide diffusion of ownership of capital, land and houses, at anti-trust legislation and the like. But if they conclude that the trend has run its course (and there are some grounds for this belief) then public ownership and control of large-scale industry with the State alone engaging in international trade might well be the policy to pursue. The choice is not an easy one to make. It is disquieting that the most vocal of the planners seem unaware that choosing is a necessary preliminary of action.

J. G. SMITH.

THE BIBLE EXAMINED

In Search of the Real Bible

By A. D. Howell Smith. (Thinker's Library, No. 98.) Pp. v+120. (London: Watts and Co., Ltd., 1943.) 2*s*. net.

TO the question, What is the real Bible ?, the answer is that it resembles an ancient city site where many cultural strata exist one below the other. If the archæologist digs deeply, he will discover some very primitive remains, while nearer the surface lies more recent, and perhaps more advanced, material. Thus Mr. Howell Smith has no difficulty in unearthing some primitive and, to us, unpleasing elements in the Bible—deceptions, obscenities, and barbarities of various kinds. This should shock none but the Fundamentalist, who cherishes a preconceived and untenable idea about the Bible ; the well-informed man knows that all primitive literatures display parallel traits. It is equally easy to show that the biblical cosmology and science are no longer tenable ; though it would be an error to imagine that only one cosmology exists in the Bible. Of the Deity, varying conceptions are present in the Bible, as Mr. Howell Smith shows, and as one would expect from this fairly complete record of a development of religious ideas, which is what the Bible is.

Mr. Howell Smith supplies the reader with a clear and quite fair summary of the results of what is known as the Higher Criticism. He is inclined to overstress the divergences of opinion among scholars, who are pretty well agreed as to "the approximate dating, mode of composition, and historical value of the different books". Only the mentally indolent will be "bewildered" or reduced to believing "that perhaps the Fundamentalists are right in dismissing all biblical criticism as a mass of arbitrary speculations". For this reason it is to be regretted that Mr. Howell Smith did not include a brief description of the methods of the biblical critics, which are indeed very simple. There is nothing abstruse or recondite about them.

Mr. Howell Smith pays tribute to the high cultural value of some parts of the Bible. "The Canon of the Hebrew Prophets contains some of the most exalted literature mankind has produced, and many of its pages are afire with hatred of oppression and injustice". *Job* is "one of the greatest literary achievements in the world". *Ruth* is "a charming tale of loyalty and kindness". *Jonah* teaches "lessons of mercy and forgiveness". With regard to the last book, it might have been added that here alone in the Bible is displayed a delicate sense o humour.

Not the least interesting chapter of the book, "The Spade and the Critic", discusses the bearing of recen archæological discovery on the historicity of the events recorded in the Bible, and upon our knowledge as to the sources whence certain biblical ideas were derived. Perhaps most students will agree with Mr. Howell Smith that Sir Charles Marston's recen attempts to make the stones of Egypt and Mesopotamia refute the critics have not been very successful.

Of course one's estimate of the value of the Bible will depend very much upon the estimate one hold of the value of religion as an element in human culture. Mr. Howell Smith would not appear to place that value very high ; and this necessarily involves a certain lack of sympathy with his subject But apart from this defect, Mr. Howell Smith ha written an informative little book.

J. C. HARDWICK.

AGRICULTURAL CROPS OF THE UNITED STATES

Field Crops

By Prof. Howard C. Rather. (McGraw-Hill Publications in the Agricultural Sciences.) Pp. ix+454 (New York : McGraw-Hill Book Co., Inc. ; London McGraw-Hill Publishing Co., Ltd., 1942.) 26*s*.

THIS book sets out to describe the general principles underlying the cultivation of the principa agricultural crops grown in the United States, in form suitable for first-year students in agricultural colleges. The book covers the principal America crops very evenly. It includes pasture and meadow management and the growing of leys and forag crops, particularly leguminous ones, with their attendant problems of grazing control, hay- and silage making and seed-production. The cereals and pulse grain crops, and the typical American crops o maize, tobacco and cotton, are naturally dealt with but potatoes and sugar beet are the only root crops discussed, the typical British root crops—mangolds swedes, turnips and kale—not being mentioned.

The text is always clear and straightforward, and well supplied with actual examples, tables, figure and illustrations. The great difficulty of the subjec is that the general principles underlying the variations in the actual methods of growing a particular crop over an area the size of the United States are sti only imperfectly understood, and this difficulty is reflected in the book ; for the general principles ar often only implicit in the text, so that a student unfamiliar with the conditions in the various State will sometimes have difficulty in appreciating the factors controlling the cultivations used. The value of the book is that it contains in one volume materia that is either only obtainable in encyclopædias and in a mass of separate bulletins, or else is only cursorily dealt with in the elementary agricultural books

E. W. R.

A TECHNOLOGIST LOOKS AT THE FUTURE

THE address delivered by Dr. C. R. Burch on the occasion of the presentation to him on pril 9 of the nineteenth Duddell Medal of the hysical Society took the form of an outline account certain advances in physical technology in which e has taken part, set out with the view of demon- rating some of the circumstances and conditions hich made those developments possible.

"These may perhaps illustrate the kind of conditions at we have to establish in the future, if we want ood technological progress to be made in Great Britain. nd it is vitally important that we should stand in the chnical forefront—at least as important in the com- g peace as in the war. Here is something we can- ot afford to neglect: whether we like it or not, hether the politicians like it or not, technical pro- ess, more than any other controllable factor, is shaping our brave new world. We have to produce contribution at least as constructive as that of our llies: if we fail in that, we shall not keep their spect, and if we do not keep their respect we shall rtainly lose their alliance."

Dr. Burch's story opened about twenty years ago, Metropolitan-Vickers, when Dr. T. E. Allibone as working on the preparation of zirconium as the asis of a long-term programme devised by Dr. . P. M. Fleming. Zirconium was known in powder rm, and the investigation aimed at producing it in herent metallic form, with the view of examining s properties. The question of industrial use was a m prospect; the immediate task was to gather owledge. It was decided to try the induction rnace, and it proved successful; but so far as uld be seen at the time, neither the metal itself r alloys of it were of any commercial value. Never- eless, the effort had not been wasted time, for it d produced a team of three men, Allibone, Burch d Ryland Davis, who had gained considerable owledge and experience of vacuum work, high- equency technique and the application of H.F. cur- nts and induction heating, together with "some- ing of the artist's sense of enjoyment, emotional ive, call it what you will, that arises from widening e range of one's experimental inquiry".

Ryland Davis and Burch continued with the de- lopment of induction furnaces, leading to a $\frac{1}{4}$-ton rnace which would melt brass or copper at 50 cycles steel at 500 cycles in place of the million cycles cessary in their earlier furnaces.

"The coil for this furnace was about the size of small dustbin—a coil of one layer of 1 in. × $\frac{3}{16}$ in. pper strap, wound on 'high edge'; 130 turns of in a length of 24 in. or so. It had to be water- oled on the outer edge of each turn, so as to leave radial thickness of 1 in. of solid copper on the side of the coil. The Transformer Department ound the coil for us. But we had to tackle the water- oling ourselves. This we did by adapting a device lled a 'mica undercutter' to mill a semicircular oove round the outside of the coil, and in the groove e soldered sixty lengths of $\frac{1}{8}$ in. copper tube—a tal of about 200 yards of it, providing sixty separate lets and outlets so that enough cooling water could got through the coil to remove the 30 kW. resist- ce-loss that occurred in it, when it was used on ass, or the rather smaller loss which occurs in it hen it is used on steel. I should like to record our thanks to Mr. Hutchinson, now of Sir George Thomson's staff, who helped us solder that interminable joint. I do not say that coil was a thing of beauty. But it did its two-fold job. Here may I touch once more on the future?

"Let us do all in our power to make it possible for the embryo physicist of the future to satisfy fully any desire he may have to acquire knowledge of crafts and skill in the use of tools. I cannot assess too highly in this respect the education I received at Oundle School. I use deliberately the phrase 'education' in the use of tools rather than 'training' because again and again I have been struck by the extent to which such craftsmanship and manual skill as I possess has helped me to form happy personal relations rapidly with all sorts and conditions of men. As that is an extremely important part of life, I am not going to apologize for digressing into a brief analysis of the operative factors. On the conscious level, the existence of a common manual skill or craftsmanship provides a link of mutual respect, and mutual respect is almost invariably an essential prerequisite to friendship. On the unconscious, or as some psychologists prefer, unwitting levels, the acquisition of a similar craftsmanship provides a number of similar links between ideas, and, what is far more important, similar links between ideas and emotions, so that similar emotions are the more readily aroused, and similar ideas the more readily 'intuited'—in short, the two men are the more readily in sympathy. Of course, if the skill has been acquired reluctantly under compulsion, any related idea is the more likely to arouse the emotion of hostility, and the idea of hostility, and even, at a higher level of mental integration, something far worse—the ideal of hostility. For that reason I would not for one moment advocate imposing in the sacred name of education compulsory courses in workshop practice for all and sundry, or even for all physicists. No! That isn't my 'ideal' at all. Rather would I see courses of this type run simply for such as care to attend.

"I should like to touch on two other aspects of the value of work with one's own hands. First, in design: in my experience it has only been physicists who do not make their own apparatus who have been apt to persist in designing things that are quite incredibly difficult and expensive to make—difficult out of all proportion to the very small gain associated with the design in question. When you explain this to them, they see the point, and not without a certain bitterness do they complain that they must keep a conscious and exhausting watch for pitfalls of construction which those 'educated' in the use of tools very largely avoid as it were unconsciously and reflexly, by sympathy."

The 500-cycle $\frac{1}{4}$-ton steel furnace being made, it had to be shown that it could be used to make alloy steels. In the face of the scepticism of practical steel-makers, the difficulties of 'teeming' the molten steel were overcome, and the 'electric fountain' effect, due to the magnetic field of the coil acting on the eddy currents in the molten charge and causing the metal to well up in the centre and run down at the sides, was found not to distribute small particles of slag through the metal. All this took more than a year to accomplish, and useful information on 'chilling' and 'burning' of cast metal was obtained.

Dr. Burch emphasized here that although Ryland Davis and he made part of the first $\frac{1}{4}$-ton furnace with their own hands, and supplied in some measure inspiration and technical leadership, the development, even at this stage, had only been possible by the co-operation of many others in the Research Department and in other parts of Metropolitan-Vickers. By 1934 there was installed in Sheffield a total induction-furnace capacity of 13 tons of furnaces capable of simultaneous running, and 6,000 kW. of generators. By 1939 this had risen to 38 tons and 16,000 kW. of generators. As the power consumption is about 600 kWh. per ton, this means that in 1939 Sheffield could turn out 600 tons per day of induction furnace steel.

"Thus the part played by Ryland Davis and myself, building on the foundations laid by Northrup and others, is itself already in some sense out of date, and is but another foundation on which a younger generation is building; and that, some say, that transitory and ephemeral aspect of technological achievement, is just what deprives it of cultural value or spiritual satisfaction. I cannot agree with that view at all. For it is the special glory of our science and its applications that the more it changes, the more it is the same thing. I am sure that all who have taken part in any technological development will have found as a concomitant of achievement a fuller realization of the underlying unity of past and present, and a lasting satisfaction of the kind that can endow even tragedy with triumph. These are matters not capable of precise definition, but expressible only in terms of mysticism and of poetry. When the subject is technology, one turns naturally to Kipling—may I remind you of his poem 'The Palace', in 'The Five Nations'?"

In the second part of his address, Dr. Burch turned to other of the end-results of Dr. Allibone's work on zirconium and its alloys. The Process and Insulation Department of Metropolitan-Vickers wanted to try the effect of a really good vacuum on the process of impregnating porous insulating materials with transformer oil, with the view of increasing the dielectric strength. One difficulty was that the impregnator had to work in a steam-jacket. The problem re-awoke in Dr. Burch an interest in distillation as a process worth experimenting with; in particular, vacuum distillation, if approached from the kinetic theory aspect, seemed promising, as a means of distilling substances which had not hitherto been distilled.

Accordingly, Burch, in association with Watts and Bancroft, constructed a vacuum still in which the condensing surface took the form of a cooled roof immediately above the evaporating pool of liquid, so that rate of distillation is limited only by rate of vapour creation. There was something of the 'heads-I-win, tails-you-lose' about the experiment, for either substances would distil in this still (and that would be useful in chemistry), or else they would not (and hence had very small vapour pressure and would be useful as sealing compounds for vacuum joints). After using the still for a week or so, the fascinating idea came to Dr. Burch that, since lubricating oil distilled in this still at temperatures 100° C. or so higher than that required for mercury, it might replace mercury in a condensation pump, and so dispense with 100° C. of artificial refrigeration in making high vacua. This made possible high-power demountable valves and X-ray tubes.

"So once more there were developments involving the co-operation of a great number of people. Dr. Allibone decided to develop demountable X-ray tubes, and eventually made the million-volt tube of the High-Voltage Department of St. Bartholomew's Hospital: Mr. Bancroft, Mr. Preece and Mr. Burrows made the pumps and the continuous vacuum still to make the oil for the pumps, and the vacuum stil with which Carr and Jewell of British Drug Houses first distilled vitamin A—for a wider group is involved than simply that of Metrovick. Further, we were not the only team to experiment with molecular distillation. While we were making our first still and quite independently, Dr. K. C. D. Hickman of the Eastman Kodak Co. in Rochester, N.Y., was tackling similar problems in very much the same way. Other teams from British Drug Houses, Imperial Chemica Industries, Shell-Mex and the Bataafsche Petroleum Mij. also co-operated in the development of application of molecular distillation.

"Returning to my own special interest—valves I made demountable 3-electrode valves, while my brother developed a 30 kW. demountable 4-electrode valve, which was so far as I know the first screen grid valve of that power made in Great Britain I should like to acknowledge our great debt to our colleagues in this work, Mr. Ludlow, Mr. Phillips Dr. Sykes, until his translation to the Nationa Physical Laboratory, and Dr. Dodds: if it was our privilege in the beginning to have given in some measure inspiration, it was their collaboration that made the development successful, and their inspiration that has carried it on. I should like also to express our gratitude to the radio staff of the Genera Post Office for their unfailing co-operation during the 'teething' troubles of demountable valves in the Rugby radio station.

"I have spoken of the co-operation of a team. But what of the man behind the team? Here should like to say specifically: All that my colleagues and I at Metropolitan-Vickers have achieved in this work, we owe ultimately to Dr. A. P. M. Fleming That raises the question: What of the future? How shall we choose men to do the kind of job that Dr Fleming is doing?

"I do not believe that a scientific man keenly interested in personal research is likely to be the bes man to choose for that kind of administrative work because his emotions will in general be too firmly linked with his personal research, and he will find it too difficult to dissociate these emotions in making judgments on points of policy. I think that a scientific man who has ceased to be interested in persona research may well develop the qualities needed for deciding questions of policy in long-term research especially if he retains or acquires an interest in the personalities of research workers, for I have the strong impression that the question of whether a particular line of work will or will not prove fruitful for a given organization may often be determinable less by logica than by psychological considerations. But, above all, avoid appointing a 'man of mature judgment'—and that phrase I take to imply a man whose judgments are determined entirely by his emotions whose emotions are keyed indissolubly to the events of his remote past, and who is totally unreceptive to new ideas except in so far as they may arouse fortuitously the emotions belonging to a bygone age

"I have touched on the psychology of the research worker, and that brings me to the question, What are the factors which determine whether a man shal be likely to have original ideas on a given subject and be keen to work on it? For a knowledge of these factors may well influence our policy in the education of research workers. I have just one suggestion to make : it is that at any rate for an appreciable percentage of researchers—I do not say for them all—we have to do with a factor which the psychologists ike to refer to in German (possibly because it is so marked a characteristic of the German nation) : a *Wiederholungsdrang* : a repetition urge : a tendency o repeat patterns in life. I would suggest, then, hat scientific or technological researches tend to be n some sense grown-up variants of some more youthful form of activity. If this is so, to find the ultimate foundations of success in research, we may well have to go back beyond the university—to the public school, or even to the preparatory school. Here I should like to acknowledge once more the very great debt that I owe to Oundle School, particularly in that they let me experiment with the small-scale semi-technical distillation of coal tar, because I wanted to. Coal tar at atmospheric pressure, 1918 : oil in a vacuum, 1928 !

"What of education in the future ? I look on it as an important indirect contribution to our long-term esearch policy to provide in our schools facilities for the keenest, at any rate, to follow up almost whatever kind of extra-curricular activity may strike their interest—and this without binding themselves in any way as to their future careers. This foretaste of achievement in following up individual interest provides, I believe, the strongest possible stimulus to education, and if the nature of the interest should change, the stimulus remains the same. The cultivaion of enthusiasm I take to form the first requisite in that far-sighted educational policy and that courageous long-term research policy to which I look forward in the future, after the War."

AGRICULTURAL DEVELOPMENTS IN THE U.S.S.R.*

By SIR JOHN RUSSELL, F.R.S.

PRIOR to the Revolution three systems of farming were practised in the U.S.S.R. : (1) large states ; (2) small peasant farms ; (3) peasant land armed by the peasants under the *Mir*, the village council or commune of very ancient origin.

Some of the large estates were run on good modern ines, some were put into the hands of managers whose business it was to extract all they could for the wner, others were moderately well managed. The easant farms were small holdings owned by the ndividual farmers, which had resulted from the arious agrarian reforms, the most important of the ater ones being those of Stolypin (1905), who had a Danish adviser and was aiming at the Danish model. The peasant land under the commune (*nadiel* land) belonged to the body of peasants but not to any individuals ; it was parcelled out into many strips which were periodically distributed by the *Mir* among the peasants in accordance with the size of family, etc. These strips were scattered over the whole area so that each man should have his share of good and of bad soil. In the time of the Revolution it was estimated that about 45 per cent of the cultivated land was in the hands of the peasants.

All three systems were disliked by the Bolsheviks, the first two because they involved private ownership f land, and the third because of its grave inefficiency and the utter impossibility of introducing modern improvements. The Bolsheviks also disliked the peasant mentality, so utterly different from that of the factory worker. The peasant wanted to sell his products at high prices while the factory worker wanted to buy them cheaply. The factory worker was accustomed to work in masses for an employer, and had before the Revolution no sense of proprietorship : the peasant was used to working alone or in small groups and always felt that he owned the land he tilled.

After some experiments, State farms were set up which accorded well with Bolshevik theory. The peasants were employees of the State receiving a weekly wage, living in great blocks of dwellings in a central area developed like a town. The whole organization resembled that of a factory, and it was expected that the peasants would develop the factory workers' outlook and become one with them. But the peasants did not like them and so they never developed : in 1938 only about 10 per cent of the cultivated land was worked as State farms, and they were used for special purposes. A completely different type of farm was set up, on the basis of the old *Mir*. The first were communes in which the whole body of workers was responsible for the full maintenance of each individual family ; but this did not answer. The *artel* organization was therefore adopted : another old Russian method which has no English equivalent. In this the workers feed and house themselves but the produce belongs to them, and after all outgoings have been met the balance is distributed according to the work done. The workers are paid in actual produce : mostly grain, potatoes, and vegetables, these being the main constituents of the peasants' dietary ; usually also there is hay for the workers' animals, and a small amount of cash. This method after suitable modification proved much more acceptable, and by 1939 a very large part of the cultivated land of the U.S.S.R. was farmed in this way.

The farms were called 'Collectives'. All the cultivated land in the village, whatever its previous ownership, was thrown into one big farm : it might be 1,000–4,000 acres or more, but was not usually unmanageable in size. All the peasants of the village could come into the group, but preference was given to the so-called 'poor peasants'. The plan of production was until just before the War sent from headquarters : it had been discussed during its development, but once settled, it could not be further discussed. The workers elected a committee to carry it out and to allocate the tasks to the different people ; the chairman, however, was not freely elected as he had to be accepted by the Party and the Government ; he often came from outside and did not usually stay long. The Party always insisted on keeping its hold on the farms, and it had its representative, who was quite independent of the committee.

Payment was always by the piece ; a certain job of work was called a "labour day", and when a man had done this he was credited with one day's work. Not infrequently about two hundred would be done during the year, but specially good workers would put in many more. The worker could eat his share of the produce or sell it to the farm, the Co-operative or in the peasant market.

The workers' share of the produce varied with the yields and the outgoings. The Government's share has varied. For some time prior to 1939 it was a fixed amount per acre of winter grain sown, and of spring grain ordered to be sown, also a fixed quantity of milk and meat per animal kept. A small price was paid, much below the market price. In 1939 more latitude in planning was allowed so long as the stipulated Government share was duly delivered. As this was fixed while yields were variable it is impossible to state any definite percentage; but an average of a number would lie between 15 to 20 per cent. Then the machine tractor station, the Government organization that hired out the tractors, combines and other big tackle and supplied the drivers had to be paid: this might take another 15 per cent. Seed for next season and fodder for winter had to be set aside: this also might amount to about 15 per cent. Insurance, administration, sick and needy people, maintenance, capital developments, and other farm overheads had also to be provided for. One way and another, more than half the produce would go, and the workers' share might be 40 per cent or less.

---

* Substance of a lecture at the Central Council for Health Education Summer School held in London during August.

A great change in the system, and in the peasants' attitude to it, came when the Constitution of 1936 gave the collective farms the use of their land for ever, and also gave each member the use of his cottage and its garden and a holding varying from ½ acre to 2½ acres on which he could keep such animals as he and his family could look after. So popular were these holdings that by 1939 much of the peasants' time was spent on them and a large proportion of the livestock of the U.S.S.R. was their private property. So decrees went forth that they must put in a minimum of a hundred days per annum on the farm; this number has since been raised.

There is little doubt that when peace returns this modified system will be able to provide the U.S.S.R. with the food needed for a rising standard of life. The theoretical objection still remains: the peasants are not employees and do not come under the labour code: they have, for example, no trade union and are ineligible for old-age pensions. 'Peasant-mindedness' still continues and they are not one class with the factory workers. But so many theoretical difficulties have been brushed aside in the U.S.S.R. for a realistic solution that we may expect this also will disappear and the system will become wholly acceptable.

PREPARATION OF A GIANT STRAIN OF *Torulopsis utilis*

By DR. A. C. THAYSEN and MURIEL MORRIS
Chemical Research Laboratory, Teddington

IN the microbiological synthesis of protein it has been observed that the complete separation of the yeast produced from the fermented wort offers certain difficulties when *Torulopsis utilis* is used as the active organism. These difficulties are due primarily to the considerable variation in cell-size of the organism, some cells being as small as 3 μ × 5 μ, or less than half the size of the average cell of this organism. Moreover, these smaller cells appear to be particularly numerous towards the end of the fermentation period, when they represent quite an appreciable percentage of the total. Since they remain more tenaciously suspended in the fermented wort than the larger cells, they easily cause a drop in yield when the yeast is separated in the centrifuge or the filter press, through the filter cloth of which they pass more readily than the larger cells. It was felt that if a method could be devised by which the size of the cells of *Torulopsis utilis* could be permanently increased, the manufacturing difficulties referred to might be largely overcome.

It might be anticipated that the most likely way of producing a strain of *Torulopsis utilis* with cells larger than the standard would be by treating the original strain with colchicine, but Blackslee's[1] and Richards'[2] attempts at influencing the nuclear divisions of various mycelium-producing fungi, bacteria and strains of *Saccharomyces cerevisiœ* in this way were unfortunately not encouraging, as they gave entirely negative results. There seemed little hope for expecting, therefore, that success might be achieved with *Torulopsis utilis*. However, it was felt that an attempt should be made to determine the effect of colchicine on *Torulopsis utilis*, if for no other purpose than to confirm that Richards' observations on strains of Saccharomyces apply equally to the non-spore-forming *Torulopsis utilis* type of 'yeast'.

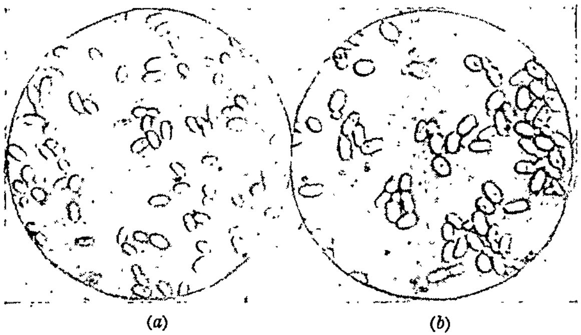
To do so a set of experiments was carried out in which increasing quantities of colchicine, from 1 mgm. to 100 mgm., were added to ordinary wort agar which was poured into Petri dishes, each seeded with about a hundred cells of a fresh culture of *Torulopsis utilis*. The various plates, as well as one or two control plates of ordinary wort agar without colchicine addition, were incubated at 30° C. and the time noted for colonies to appear. In addition, the number of colonies on the plates were counted and the rate at which growth progressed noted.

Even at colchicine concentrations of 100 mgm per 10 ml. wort agar, no influence could be detected of an action of the alkaloid on the growth of *Torulopsis utilis*, and measurements taken of the size of the cells differed in no way from those of cells of the control strain grown on ordinary wort agar. The observations of Blackslee and Richards therefore apply also to *Torulopsis utilis*, the nuclear functions of which whatever they may be, remain unaffected by colchicine.

Recently attention has been directed by Bauch to substances other than colchicine which influence mitosis and may give rise to the production of giant cells. Among these substances is α-naphthylamine

The effect of this substance on the cells of *Torulopsis utilis* was studied by us in a series of experiments in which increasing amounts of this chemical were added to wort agar, afterwards seeded with *Torulopsis utilis* cells in numbers to yield approximately a hundred colonies per test culture. Starting with 1 mgm., the concentration of α-naphthylamine was gradually increased to 60 mgm. per 10 ml. of wort agar. It was observed that quantities up to 20 mgm of α-naphthylamine had no influence on the numbers of colonies appearing on the test plates after incubation at 30° C., nor could any change be seen in the size of the cells produced. On the plates containing 25 mgm. and 30 mgm. of the chemical, only 30 per cent of the seeded cells gave rise to colonies, while the plate containing 40 mgm. of α-naphthylamine allowed only 1 per cent of the inoculated cells to grow. The plate with 50 mgm. of α-naphthylamine remained sterile. It was noticeable that the shape of the cells on the plates with high concentrations of α-naphthylamine had changed from the normal egg-shape to spherical. The volume, however, had not been increased.

A single cell of the spherical type was removed by the micromanipulator and grown in liquid wort at 30° C. The ensuing culture was found to be



(a) CELL OF STANDARD STRAIN OF *Torulopsis utilis*. × 440.
(b) CELL OF CAMPHOR-GROWN STRAIN OF *Torulopsis utilis*. × 440.

composed of normally-shaped cells. The effect of α-naphthylamine, therefore, had been transient and unable to affect the nuclear functions of the organism exposed to it.

Prior to his reference to α-naphthylamine as a mitosis-toxin, Bauch[4] had mentioned, in passing, that camphor affected mitotic changes in brewer's yeast and other fungi, resulting in the production of giant cells. Without giving details of his procedure, Bauch reported that the action of camphor resulted in the doubling of the chromosome number of the cells affected.

It was decided to study the effect of camphor on *Torulopsis utilis* on the lines previously used for colchicine and α-naphthylamine. The amount of camphor added to plates each containing 10 ml. of wort agar ranged from 5 mgm. to 50 mgm. Each of the plates was seeded with about a hundred cells of a fresh culture of *Torulopsis utilis* grown on wort agar, and incubated at 30° C.

It was found that with camphor additions of 20 mgm. or less, growth of *Torulopsis utilis* proceeded undisturbed at the temperature chosen, and there was nothing to indicate that the size of the cells had been affected. At camphor concentrations of between 25 mgm. and 30 mgm., the growth of the inoculated cells into colonies was impeded at first and could not be detected macroscopically until two days after the formation of visible colonies on the control plates. The number of colonies eventually appearing on the plates containing 25 mgm. of camphor was not noticeably smaller than that on the controls, but on the plates containing 30 mgm. of camphor only a few of the seeded cells gave rise to macroscopically visible colonies. In these colonies marked changes had taken place in the size of the individual cells, and measurements revealed that the average size (from twenty separate determinations) had increased from $3 \cdot 8\ \mu \times 7\ \mu$ for the standard strain of *Torulopsis utilis* to $4 \cdot 8\ \mu \times 8 \cdot 9\ \mu$ for the cells of the strain grown on camphor. These dimensions would correspond with a difference in volume of $326\ \mu^3$; $318\ \mu^3$ being the volume of the cell of the standard strain and $644\ \mu^3$ that of the cells of the camphor-grown strain. The accompanying photographs illustrate the difference between the size of the cells of the two strains.

By means of a micromanipulator a single cell was isolated from a colony on the plate containing 30 mgm. of camphor and subcultured in ordinary wort agar. The resulting culture was catalogued as *Torulopsis utilis* var. *major*.

Torulopsis utilis var. *major* has been subcultured over a period exceeding one year and has retained unimpaired its most significant characteristic, the increased cell volume.

Attempts have been made to increase still further the volume of the cells of the new strain by growing it on wort agar containing camphor, but without success. It was noticed in these experiments that growth of the inoculated cells on the camphor medium was temporarily impeded when the camphor concentration reached 30 mgm. per 10 ml. wort agar, and that only a few of the seeded cells eventually grew into colonies. Beyond a concentration of 30 mgm. of camphor in 10 ml. of wort agar, no growth at all took place.

The size of the cells of the developing colonies did not differ from that of *Torulopsis utilis* var. *major* cells. It was concluded, therefore, that an increase in size beyond that already achieved was impossible and that in this respect *Torulopsis utilis* differed from that of the Saccharomyces strains studied by Bauch.

Having obtained a strain with cells considerably larger than those of the original *Torulopsis utilis*, the new type was submitted to various tests in order to determine its suitability for food yeast production.

In the first place the strain was compared with the standard culture of *Torulopsis utilis* in its ability to separate from the spent wort of a fermented molasses wort. It was found that both in the centrifuge and in the filter press the cells of *Torulopsis utilis* var. *major* could be more readily separated than the cells of the standard strain. It remained to be ascertained whether the new strain possessed the valuable properties, as regards protein and vitamin content, of the mother strain and would give as large yields of yeast per unit of carbohydrate consumed as the latter.

The results of a comparative examination of the two strains are given in the accompanying table.

	Torulopsis utilis	*Torulopsis utilis* var. *major*
Size of cell	$3 \cdot 8\ \mu \times 7\ \mu$	$4 \cdot 8\ \mu \times 8 \cdot 9\ \mu$
Volume of cell	$318\ \mu^3$	$644\ \mu^3$
Yield of dry yeast on sugar fermented	59–60 per cent	59–62 per cent
Protein content of dry yeast	55·3 per cent	56·0 per cent
Phosphorus content of dry yeast	1·8 per cent	2·8 per cent
Aneurin content of dry yeast	20 μ gm. per gm.	20 μ gm. per gm.
Riboflavin content of dry yeast	60 μ gm. per gm.	60 μ gm. per gm.
Taste of dried yeast	Slightly meaty	Slightly meaty
Colour of dried yeast	Light buff	Light buff
Generation time under standard conditions of fermentation	100–110 min.	58–90 min.
Optimum temperature	30° C.	30° C.

Thus in every one of the above-mentioned characters, except those of size and generation time and possibly in phosphorus content, the two strains were identical.

The significance of the shorter generation time will be referred to in greater detail in a subsequent report, and it may therefore suffice to state here that the shorter generation time should offer advantages in speeding up the output of yeast from any given capacity of fermentation plant.

Discussion

The experiments reported above have shown that Bauch's claims to have produced giant cells from various Saccharomyces species by exposure to camphor vapours applies equally—though to a limited extent—to at least one Torulopsis species.

The increase in size of cells of *Torulopsis utilis* is limited to a doubling of their volume. Repeated application of the camphor technique leads to no further change.

The doubling of the cell volume has been found to be permanent, even in cultures of the new strain which have not had contact with camphor for hundreds of generations, an observation which proves that very deep-seated changes have resulted from the original exposure.

It has not been possible, so far, to determine whether the increase in cell volume can be correlated with an increase in nuclear substance. Further work in this direction is contemplated. In this connexion it may be significant that in one experiment it was observed that the percentage of nucleic acid extractable from a given weight of cells of the new strain was considerably greater than that obtained from the same weight of cells of the standard *Torulopsis utilis* strain.

It is of interest also to record that the cells of *Torulopsis utilis* var. *major* show a greater tendency to autolyse than the cells of the standard strain. In this connexion, therefore, the new variety behaves like the thymus cells studied by Dustin and his collaborators under the influence of karyoklastic toxins, that is, toxins which among their numbers include colchicine but not camphor. Chodkowski[5] has given an interesting account of Dustin's theory of the functioning of karyoklastic toxins.

With the knowledge that camphor in certain concentrations is capable of producing deep-seated changes in the cell-volume of *Torulopsis utilis*, it was thought of interest to find out whether other bicyclic terpenes would have a similar effect. So far, it has been possible to show that two further members of the camphor system, borneol and bornyl acetate, and one of a different terpene grouping, camphene, are capable of inducing what appears to be the same changes in cell volume as camphor itself. The significance of this observation is being followed up.

Summary

Under the influence of camphor, the cells of *Torulopsis utilis* undergo deep-seated changes which result in the permanent increase in their volume. By such influence a new strain of *Torulopsis utilis* has been produced, and designated *Torulopsis utilis* var. *major*, which in its biochemical properties is identical with that of the mother strain, though it differs from it in certain mechanical characteristics and physiological behaviour. Further, it has been found that other bicyclic terpenes than camphor may react on *Torulopsis utilis* in the same manner as camphor itself. Colchicine and α-naphthylamine were found to be incapable of increasing the cell volume of *Torulopsis utilis*.

We are grateful to Dr. Harriet Chick of the Lister Institute of Preventive Medicine for the assay of the aneurin and riboflavin content of the two strains of *Torulopsis utilis*.

The work described above was carried out as part of the programme of the Chemistry Research Board, and is published by permission of the Department of Scientific and Industrial Research.

OBITUARIES

Dr. G. E. Pilgrim, F.R.S.

WITH the death on September 15, at Upton near Didcot, Berkshire, of Dr. Henry Guy Ellcock Pilgrim, vertebrate palæontology has lost one of its most distinguished exponents, and the world's greatest authority on the rich Siwalik fauna of India. Pilgrim, who came of an old Barbadian family, was born at Stepney, Barbados, on December 24, 1874. He was educated at Harrison College, Barbados, and University College, London (D.Sc., 1908); he was appointed to the Geological Survey of India in 1902, from which he retired in 1930, having been a superintendent since 1920. He then became a member of the supernumerary staff of the Department of Geology, British Museum (Natural History). He was elected a corresponding member of the Palæontological Society of America (1925), a fellow of the Asiatic Society of Bengal (1925), and, very belatedly, a fellow of the Royal Society (1943). He was president of the Geological Section of the Indian Science Congress in 1925. During the War of 1914–18 he was attached as 2nd lieutenant to the 125th Napier's Rifles, and received war medals for service in Mesopotamia and Persia, 1916–19.

Pilgrim's work with the Geological Survey of India can be divided into two main sections: as a geologist, and as a palæontologist. His most important stratigraphical work was divided between two problems, namely, (1) the survey of portions of Persia and Arabia; and (2) the Siwaliks and other Tertiary freshwater deposits of North-Western India, including Baluchistan.

The Persian Gulf work was done in two visits, and has been described in two *Memoirs of the Geological Survey of India* (34, Pt. 4; 1908: and 48, Pt. 2; 1924). In these two memoirs he described the geology of much country that had not previously been visited by a geologist, incorporated the work of earlier workers where this was of value, and laid down the succession of formations in Persia from Pre-Cambrian to Recent, introducing a nomenclature that has in the main been adopted by later workers.

Pilgrim was not only the first geologist but also the first European to visit parts of Trucial Oman in Arabia. He was also the first geologist to visit Bahrein Island in the Persian Gulf, which he mapped. He showed that the structure was that of a dome, and this led later to boring for oil, and a flourishing industry is now established in Bahrein.

Still more important scientifically is Pilgrim's geological work in India. The Siwalik formation, so famous for its fossil vertebrates, had not been previously subdivided, except into a lower apparently unfossiliferous section and an upper fossiliferous section. Strata 15,000–20,000 ft. thick had all been lumped together, and the fossils derived from several stages all mixed together; these fossils had been described merely as zoological specimens without any knowledge of their relative ages, except such as could be surmised by comparison with fossils elsewhere. To Pilgrim belongs the distinction that he reduced this muddle to order. He showed that there are three separate fossiliferous divisions to the Siwaliks, each with its characteristic vertebrate fossils, and in his "Preliminary Note on a Revised Classification of the Tertiary Freshwater Deposits of India" (*Rec. Geol. Surv. India*, 40; 1910), he sorts out two hundred species of Indian vertebrates among his three divisions of the Siwaliks and the underlying Nari beds, and assigns ages in terms of European nomenclature ranging from Aquitanian to Pliocene. Fifty of these species are of his own discovery. In a later paper, "Correlation of the Siwaliks with Mammal Horizons of Europe" (*Rec. Geol. Surv. India*, 43; 1913), he succeeds in splitting up the Tertiary freshwater strata of India and Burma into no less than thirteen horizons with their characteristic fossils, ranging from the Gaj below to the Boulder Conglomerate at the top of the Siwaliks. He shows the European equivalent of each horizon, and also the equivalence of the freshwater strata with the marine Tertiary beds of India. His correlation has been of immense use to all later workers on the Tertiaries of India.

Pilgrim also made an expedition to Bhutan, and wrote a joint memoir, with Mr. W. D. West, on the geology of a portion of the Simla Hills.

With the help of the late Mr. Vinayak Rao, Pilgrim added largely to the already large collections of Siwalik vertebrate fossils in the Geological Museum in Calcutta, and he thus had at his disposal an immense mass of material, partly already described in the past by Lydekker and partly new. To this material Pilgrim devoted all available time while in the Indian service, work that he continued in London at the Natural History Museum after his retirement. The total result is an impressive mass of fine memoirs in the *Palaeontologica Indica* descriptive of various groups of Indian vertebrates, of which one may list in chronological order the Giraffidæ of India (1911), the Vertebrata of the Gaj of the Bugti Hills and the Punjab (1912), the Perissodactyla of the Burma Eocene (1925), the Suidæ of India (1926), the Artiodactyla of Burma (1928), the Carnivora of India (1932), and finally the Bovidæ of India (1939). Separate mention may be made of Pilgrim's discoveries of fossil primates in the Siwaliks, comprising no less than five new species and two new genera. In his view Sivapithecus, one of these latter, was, when he wrote (1915), the closest anthropoid phylogenetically to man, with the possible exception of Pithecanthropus and Eoanthropus.

The preparation of this note has been a sad task for me, for Pilgrim, the late James Malcolm Maclaren and I travelled out to Calcutta together in 1902, on the P. and O. *Coromandel*, to join the Geological Survey of India. L. L. FERMOR.

Prof. H. G. Denham

THE death, which occurred on February 15, 1943, of Prof. Henry George Denham, professor of chemistry in, and rector of, Canterbury University College, Christchurch, New Zealand, and chairman of the New Zealand Council of Scientific and Industrial Research, has deprived the University of New Zealand of a distinguished teacher, administrator and investigator, and both the Dominion and the British Empire of a man who had done eminent public service in vigorously fostering the advancement of pure and applied science in his native country.

He was born in Christchurch on July 14, 1880, and received his early education at Sydenham School, whence he proceeded with a scholarship to the Boys' High School. Having completed his school education, he adopted school teaching as a profession, but while still engaged on this work entered Canterbury College as a student in 1901. Here he decided to study chemistry as his main subject when Dr. W. P. Evans was appointed to the chair of chemistry in 1903. He won the Chemistry Exhibition and graduated B.A. in 1904 and M.A. with first-class honours in chemistry in 1905. Having carried out an investigation on the temperature of combustion of methane in the presence of palladiumized asbestos, he obtained the M.Sc. degree and won the 1851 Exhibition Science Research Scholarship in 1906. In the same year I had the good fortune to welcome him as a research student in the Muspratt Laboratory of Physical and Electro-Chemistry, University of Liverpool. Denham's cheery and good-natured personality and his keenness and enthusiasm for research in physical chemistry were a great source of strength to the newly opened laboratory, whither a few years later were to come three other very able young New Zealand investigators—Prideaux, Farrow and Stubbs.

Denham proved to be an exceptionally gifted research student. His first work was the determination of the degrees of hydrolysis of salts in aqueous solution by means of the hydrogen electrode. This novel and pioneering piece of electrometric research led Denham on to two other very interesting lines of investigation. Having found that in the presence of the hydrogen electrode anomalous values for the hydrogen ion concentration in solutions of lead salts were obtained—results which could be explained only by the assumption of a partial reduction of bivalent to *univalent* lead ions at the surface of the platinum-hydrogen electrode—he joined forces with A. J. Allmand, then a research student in my laboratory. By means of an automatic thermo-circulation apparatus they caused a solution, say, of lead acetate, to pass constantly upwards through a hot steam-jacketed column containing metallic lead and then downwards through a cooled column (of the same solution). In this way they found that metallic lead crystallized out from the solution in the cooler part, a result which could be best explained by the reversible equilibrium

$$\mathrm{Pb}^{++} + \mathrm{Pb} \underset{\text{cooling}}{\overset{\text{heating}}{\rightleftarrows}} 2\mathrm{Pb}^{+},$$

similar to that which occurs in the case of copper and gold salts. Encouraged by this remarkable result, Denham then went on alone to apply the same method to other salts and demonstrated the existence in aqueous solution of a univalent cadmium ion, a 'subvalent' thallium ion (Tl_2^+) and a bivalent bismuth ion. In the electrometric investigation of the hydrolysis of salts of zinc, magnesium, thorium, cerium, nickel and cobalt, Denham found that very irregular and fluctuating results were obtained. These he explained by the assumption of the existence of a microheterogeneous system, that is, the presence of colloidally dispersed hydroxides or basic salts in the solution. A closer examination of these 'anomalies' led to the publication of an interesting paper. In connexion with this work it may be mentioned that Kolthoff and Kameda in 1928 explained the anomalous results as due to the adsorption of metal cations on the platinum black. The equivalent amount of hydrogen ions liberated in the solution upsets the hydrolysis measurement. The work on the hydrolysis of salts was completed by an electrometric determination (with the hydrogen electrode) of the degrees of hydrolysis in aqueous solution of the blue and green chromic sulphates.

Denham's last piece of work in my laboratory dealt with the formation of 'autocomplexes' (anionic complexes) in solutions of cupric chloride, cupric bromide and cobalt bromide, in which an ionic transport method was employed. For his excellent research work he was awarded the D.Sc. degree by the University of Liverpool. Denham then went to continue his researches in Germany, and having arrived in the laboratory of Prof. Bredig at the University of Heidelberg he informed Bredig that he wished to work for the Ph.D. degree of that University but could only spend about a year on the job. Prof. Bredig was astonished, said that such a thing was very difficult if not impossible—but he could have a shot at it if he wished! Little did he realize Denham's tremendous powers of concentration and hard work, not to mention his great insight and skill as an investigator. The result was Denham did so well that he got his Heidelberg Ph.D. in the year. His subject of investigation was a quantitative study of the reversible catalytic reduction of titanic salts by hydrogen gas (in presence of platinum black). It formed one of Bredig's great series of studies in heterogeneous catalysis.

With a record of six published papers and the research degrees of two European universities (a pretty good record for 3½ years work), Denham returned to New Zealand in 1910 and acted for a time as research student and honorary lecturer at Canterbury College. Then in 1912 he obtained a post as lecturer in chemistry under Prof. B. D. Steele at Brisbane (University of Queensland), where he was appointed head of the Chemistry Department and acting-professor during the absence of Prof. Steele on war-work in England, obtaining the title of assistant-professor at the end of the War.

In 1921 Denham published his useful text-book of inorganic chemistry, and in the same year was appointed professor of inorganic chemistry at the University of Cape Town, remaining there only two years, for in 1923 he was offered and accepted the succession to the chair of chemistry at Canterbury College, Christchurch—a post which he still occupied at the time of his death. From 1941 he held also the high office of rector of the College. During his twenty years as professor, Denham proved himself to be a very active and excellent university teacher and administrator, the much-loved father of his students, and a wise, energetic and forward-looking member of the academic body. He was a member of the Academic Board of the University from its inception in 1927, and a representative of that Board on the University Senate from 1935. Apart from his great work in University and College affairs, Denham was very active in fostering and promoting the advancement and application of science in New Zealand. He was a fellow of the Royal Institute of Chemistry of Great Britain and Ireland, an original fellow of both the Australian Chemical Institute and the New Zealand Institute of Chemistry, and a fellow of the Royal Society of New Zealand and of the New Zealand and Australian Association for the Advancement of Science. Of the latter body he was president of Section B (Chemistry) for the Hobart meeting in 1928, and Liversidge Lecturer for the Canberra meeting in 1939.

Denham took a very active and important part in the promotion and development of scientific control and research in connexion with both primary and secondary industries in New Zealand. Thus he was a member of the New Zealand Council of Scientific and Industrial Research from its establishment in 1926, becoming chairman in 1934. He was active in the foundation of the Wheat Research Institute in 1927 and chairman of its committee from the start. Denham's interest in the successful promotion of agricultural science and practice can be realized when it is stated that he was a member of the Board of Governors of Canterbury Agricultural College during 1928–41 and its chairman during 1932–38; a member of Council of the New Zealand School of Agriculture from its foundation in 1937 until 1941, and a member of the committees of the Dairy Research Institute and the Wool Manufacturers' Association.

During his stay in Brisbane and Cape Town, Denham published a number of papers on complexes in solutions of copper and cobalt salts and on the existence and preparation of the suboxides and subsalts of lead, cadmium and bismuth. Some doubt has been cast on the existence of certain of these suboxides and subhalides by the later work of Hollens and Spencer (1934), using magnetic susceptibility measurements, and by that of Hedger and Terrey (1936) using X-ray methods. Some of the substances in question were prepared by methods which Denham's work had also shown to be doubtful.

During his busy years as professor at Christchurch, Denham never lost his interest in research, and in collaboration with senior students published a number of papers on salt hydrolysis and on the ternary systems zinc oxide – nitric acid – water and lead oxide – nitrogen pentoxide – water.

The coming of the War brought new and heavy burdens. He threw himself fully into the great war effort of New Zealand, but there seems little doubt that this extra strain was too much for a man who had never spared himself in his devoted services to his students, the University, the community and science. Fortunately, he lived long enough to know of the great honour that was coming to him, namely, honorary membership of the Society of Chemical Industry.

As one of his old teachers, I have always had the highest regard and affection for him, and count it a special piece of good fortune for myself that I was able to help him at an early stage in his career. He was a great son of his native land, and a very fine example of a man who devoted himself wholeheartedly not only to the advancement of science and sound learning but also to the promotion of the health, happiness and prosperity of his fellow countrymen by the means which science can provide.

F. G. DONNAN.

Sir Michael Sadler, K.C.S.I., C.B.

THE death of Sir Michael Sadler removes from the world of education an elder statesman universally honoured for his achievement and almost as widely trusted for his wisdom. He was never, as too many of our educationists are apt to be, merely the brilliant amateur in the field, or the politician in disguise. Both these parts he could have played to perfection, if he had so chosen, for he had the gift of persuasive eloquence and great personal charm. At Oxford he became president of the Union in his second year, but made no mistake about his first classes in the Schools. Then in 1895 he settled down to the Oxford University Extension work, shaping in a very short time the main lines which it has since followed. He passed on almost at once to spend eight years as director of special inquiries and reports at the Board of Education, and used the opportunity to conduct a thorough study of what was being done outside Great Britain, particularly in Prussia and generally

Germany. It was a period in which he not only tended his own knowledge far and deep, but also oduced a series of vitalizing documents which gave nfidence and purpose to the educational movement ich began in 1902. In that year it can be safely serted that no Englishman knew more about educa- on at all its stages in all the countries that mattered an Sadler, and certainly there was no one more pable of expressing what he knew. It was natural at his knowledge and powers should be freely used. one hand he became for a brief period professor the history and administration of education at anchester, and then vice-chancellor of Leeds; on e other, he found time to plan the secondary and gher education of Sheffield, Liverpool, Birkenhead, uddersfield, Exeter, Newcastle-upon-Tyne, Derby- ire and Hampshire. This series of signal public rvices culminated in his presidency of the Calcutta iversity Commission and his monumental report Indian education. His long apprenticeship had rne abundant fruit, and all of it came to maturity. ter, he returned to his old University as master University College, continuing to be until his retire- nt and after it a source of inspiration and life in e many causes to which he laid his hand: in the niversity and in the City, of which he became a eeman; in the Oxford Preservation Society; and in movements for the encouragement and better derstanding of modern art and promising artists.

He could deliver a formal oration of perfect classical m, and equally could speak with eloquence and e on the spur of the moment in a company large or all. He had the gift of throwing his entire self into atever engaged his interest, and partly because this he won the devotion and admiration of many ung people. He radiated friendliness, and it was t for nothing that Leeds during his vice-chancellor- ip was spoken of as "the friendliest in the country". attracted youth also because he was little in- ested in what was already established and con- ntional, but was ever looking for promise and the ovement of the future. It is significant of this ality in him that at Headington his fine Gainsboroughs were not given pride of place, but were kept in the shade by his remarkable collection of modern examples, which much resembled the wheat and the tares alike growing together for the harvest; and it must be confessed that he liked to shock convention to the extent of advancing paradoxes in which he did not entirely believe himself. It has been said that the Greeks were always children, and Sadler in the same way kept something of the eternal boy. He told a select gathering of heads of houses at Oxford that in a generation Oxford and Cambridge would be moss-grown relics of the past, and the intellectual life of the country would have passed to Leeds, Manchester and Birmingham. He blandly advocated a by-pass to bisect Christ Church meadows, partly because he liked by-passes as being strong, broad and direct, like himself, and partly he wanted to observe the shock with which Oxford would react to this assault on one of its most treasured beauties.

He had a happier life than is given to most: he has left us the record of a great and lovable man.

CYRIL NORWOOD.

WE regret to announce the following deaths:

Prof. Leon Asher, emeritus professor of physiology in the University of Berne, on August 8, aged seventy-eight years.

Prof. H. L. Lebesque, For.Mem.R.S., professor of mathematics in the Collège de France, during 1941, aged sixty-eight.

Prof. Einar Lönnberg, the well-known Swedish zoologist, on October 21.

Mr. Cecil Rowntree, the distinguished surgeon and authority on cancer treatment, on October 14, aged sixty-three.

Sir Aurel Stein, K.C.I.E., F.B.A., the authority on Central Asian antiquities, on October 26, aged eighty.

Mr. W. P. Westell, formerly curator of the Letchworth Museum and well-known lecturer and writer on natural history, on November 1, aged sixty-eight.

NEWS and VIEWS

oodwardian Chair at Cambridge: Lieut.-Colonel W. B. R. King, O.B.E., M.C.

LIEUT.-COLONEL W. B. R. KING has been appointed oodwardian professor of geology in the University of mbridge. He has the unique distinction of having en the chief representative of British geology ectly employed as a geologist in both world wars. won two awards on the Western Front: an B.E. for geological services in the War of 1914–18, d an M.C. for non-geological actions connected with e evacuation of the British Army from France in 40. In peace, Colonel King was a member of the ological Survey of Great Britain from 1912 until his pointment as Prof. Marr's assistant at Cambridge in 20. Eleven years later he was elected to the Yates- ldsmid chair of geology at University College, ndon.

Colonel King's publications are an index to his wide erests. Among them we find contributions to læozoic palæontology and stratigraphy, largely awn from the north of England and Wales, but in- ding also descriptions of fossils from the Middle East and India; gleanings from his war experience of the Mesozoic and Tertiary formations of the Continent; interpretations of North of England scenery; and a co-operative excursion into the marches of geology and archæology, so well represented in the Pleistocene of the Thames Valley. Colonel King's past experience on the Geological Survey has given a special character to his open-air teaching of his subject. In another direction, he will be remembered as a popular secretary of the Geological Society.

New Master of Birkbeck College: Prof. H. Gordon Jackson

WITH the appointment to the mastership of Birkbeck College, London, of Prof. H. Gordon Jackson, who has been head of the Zoology Department there since 1921 and professor since 1928, the Governors seem to have followed a similar course as towards the end of the War of 1914–18, when the late Dr. Senter was appointed to that position. Thus during the important period of reconstruction which the College looks forward to after the War, there will be in charge one who is familiar with the rather special conditions which obtain there. To zoologists Prof. Jackson is best known for his numerous papers on the systematics of the terrestrial Isopod Crustacea and on the comparative anatomy of the Isopod head; but his colleagues are familiar, too, with the imperturbable good humour, the careful planning and the absolute fairness with which he has presided over numerous bodies in his College and University, while large numbers of former students recall with great enjoyment the lucidity and wit of his lectures, and his uncanny knack of selecting precisely the most apt metaphor or simile for driving home a point of difficulty. In view of the damage sustained by the College during the raids of 1940–41 and the part which Birkbeck College is bound to play in University education after the War, the transfer of the College to the Bloomsbury site is one of its most urgent problems. Prof. Jackson's many high qualities will, we feel, ensure an early solution.

Tercentenary of John Bainbridge

When Sir Henry Savile (1549–1622), while holding the post of warden of Merton College, Oxford, founded the Savilian professorships of geometry and astronomy at Oxford in 1619, the first of these was given to Henry Briggs (1561–1630), who had held the chair of geometry at Gresham College, London, while to the second was appointed John Bainbridge, a London physician who had just published a description of a comet observed in November 1618. Bainbridge on his appointment was thirty-seven, and he continued to hold his chair until his death on November 3, 1643. Born at Ashby-de-la-Zouche, he had studied at Emmanuel College, Cambridge, and had qualified in medicine. While teaching and practising he devoted his leisure to mathematics and astronomy. Removing to Oxford in 1620, he continued his study of the writings of the Greeks and Arabs, and though he published but little, he left a considerable number of manuscripts. These he bequeathed to his friend, the learned but unfortunate Archbishop James Ussher (1581–1656), whose library, after various vicissitudes, passed to Trinity College, Dublin. Bainbridge died at his house opposite Merton College, and after an oration by William Strode, his body was laid beside that of Briggs in Merton College Chapel.

Aeronautical Medals

The Royal Aeronautical Society has recently acquired, through the generosity of an anonymous donor, a remarkable collection of more than three hundred aeronautical medals, dating from 1714 to 1941. The medals are a veritable history of aeronautics, struck on the occasion of some aeronautical event. Three of the early medals were struck in 1783 to commemorate the first ascent of the Montgolfier Brothers in a hot-air balloon; two others show the first ascent of Lunardi from London in 1784; another the first Dutch aeronaut to ascend, from Amsterdam, in 1806. James Sadler, the first Englishman to make an ascent, is commemorated in a medal dated 1811. A silver medal of 1851 shows the ascent of three balloonists each on a horse! There are many examples of the Siege of Paris medals of 1870, Giffard's ascents and others. A bronze medal of 1896 shows the Andrée polar balloon, and several silver ones of 1901 Santos Dumont's dirigible. Coming to later days, there is a medal of 1909 commemorating the award of the Congress Medal to the brothe Wright; medals of various Zeppelins, Parseval, t *R*.101 and other dirigibles; medals commemorati Bleriot's cross-Channel flights, 1909; the flights Paulhan (London–Manchester, 1910); Chavez (cros ing the Alps, 1910); Lindbergh (trans-Atlant flight, 1927); Hinkler (London to Australia, days, 1928); Kohl, Hunefeld and Fitzmauri (Ireland to America, first east–west flight, 1928); a Prof. Picard and Dr. Kipfer (first stratosphere asce 1931).

Collaboration in Fuel Research

The Standing Consultative Conference on F Research, which has been constituted by the Depa ment of Scientific and Industrial Research to p mote collaboration among the various resea associations or equivalent organizations engaged fuel research, and between them and the Departmen Fuel Research Organisation, had a preliminary me ing on October 21 at which representatives of Ministry of Fuel and Power, the British Coal Utili tion Research Association, the British Electrical a Allied Industries Research Association, the Brit Refractories Research Association, the Gas Resea Board, British Iron and Steel Federation (Indust Research Council), and British Hard Coke Resea Association were present. In his opening rema Sir Edward Appleton, who presided, briefly descri the objects which the Department had in view setting up the Conference, and emphasized t membership is voluntary and at the invitation the Department. The Conference is intended provide a convenient means whereby the resea organizations may keep in close touch with e other, and assist each other by interchange of formation and by friendly discussion. Members the Conference described briefly the aims and sc of their organizations and then discussed arran ments for the setting up of a central body to und take the preparation and publication of abstracts current literature relating to fuel and the maint ance of a register of translations. It was deci that the next meeting should be held early in Janu 1944, when the fuel research programmes of the m ber organizations would be considered by Conference.

Application of Biology to Agriculture

Dr. Hubert Martin's presidential address to Association of Applied Biologists, delivered on Feb ary 12, 1943, which has now appeared in the *An of Applied Biology*, pays tribute to the work of Biology War Committee and expresses the view t the provincial advisers in the biological subjects soon be expected to assert their proper and powe influence on the activities of the War Agricult Executive Committees. Discussing the official re nition of proprietary pest control products, w has been brought into fresh prominence through participation of the advisory services in the "Gr more" campaign, Dr. Martin outlined the nego tions between the Association and the Bri Mycological Society, the Ministry of Agriculture the Association of British Insecticide Manufactu which had led to the scheme announced in Oct for a joint panel to give the requisite guidanc the advisory committee. The further growth of scheme, which will not admit products of w secret composition and which includes no te ganization, is dependent on the goodwill of those ncerned in its operation, and Dr. Martin regretted at no provision was made for the direct representa- n of the Association of Applied Biologists or of e advisory services on the organization.

In Dr. Martin's opinion, personal contact is the yal road to the full application of biology to agri- lture, but for the grower the printed or written rd is the best form of memorandum. After citing stances of the failure of the results of research to transmitted in proper perspective to the grower, . Martin commended to the Agricultural Improve- ent Council the appointment of a corps of intelli- nce or public relations officers. Such officers should journalists acquainted with both practical and entific aspects, able to translate research into vivid rkaday English, wise enough to avoid sensa- nalism and to seek expert advice on their scripts fore publication. To foster mutual confidence they ould move freely among growers, advisory officers d research workers.

sponsibilities of Scientific Societies

THE latter part of Dr. Martin's address is devoted the wider questions of the post-war responsibilities the Association of Applied Biologists, particularly presenting a common front with other scientific en to guide the application of science. Science, he id, must protect itself from exploitation and must o accept responsibility not only in safeguarding manity against such misuse, but also in ensuring at mankind shall profit to the full by the impact science. In furtherance of this, Dr. Martin suggested bdivision of the Society not on a geographical but a subject basis, each subject group dealing with e applied aspects of one particular branch of ology. The subject groups would then serve to k together all biological sciences in an organiza- n capable of exerting a unified pressure, yet bound t by rigid rule or order but by common interests d responsibilities. He believes such a method uld provide for collaboration with the academic cieties without necessitating the segregation of non- thological members of the Association in accordance th W. C. Moore's suggestion to the British Myco- gical Society. Moreover, it could also be made to rve the unification of science by counterbalancing e economic tendency of the larger publishing cieties to lose contact.

Discussing further the formation of a united entific front, Dr. Martin believes that this is more ely to be achieved with the publishing societies ther than the professional societies as the basis for organization. He visualizes a Science Council on hich the sciences would be represented by election m the publishing societies. Such a Council should, urged, set up a main committee with sub-com- ittees in the different sciences, which, with philo- gical representation, would extend the work on menclature to that of terminology at its broadest. s task would be to guide the evolution of language d to add to its precision as an instrument of science. e pleaded also for a simplification of spelling, but en more important than a common language is the sk of training humanity in those principles to which ience itself is dedicated. The primary task of the mmonwealth of Science is to convert mankind to e methods and ethics of science; to train the ung in the discipline of science; to instil into atesmen and politicians the spirit of science and to ow commerce that there is more profit in the full application of science than its exploitation. This would involve a fundamental change in the status of the sciences in education and a change in the attitude of the scientific hierarchy towards the political responsibilities of science. He thinks that the danger of fundamental science becoming neglected is illusory, but he deplored any industrial pressure which restrains publication of knowledge. Patent laws encouraging such restriction should be repealed. The danger of falling from scientific grace is no reason for monastic seclusion and for refusal to participate in building up a science front strong enough to withstand any form of pressure, or to correct political and industrial offences against scientific interests and principles.

The Lister Institute of Preventive Medicine

THE report for 1943 of the Lister Institute of Preventive Medicine marks the fiftieth anniversary of the beginning of its scientific work and records work of a quality which reflects great credit on Sir John Ledingham, who has recently retired from the directorship, and on all his staff. The war-time dispersal of some of the staff to other laboratories may have its disadvantages, but it must have brought advantages also through the closer contacts made with other workers. For thirty-eight years Sir John Ledingham has been a member of the staff of the "Lister", and thirteen years ago he succeeded Sir Charles Martin as director. These are two names respected by every man of science; they both call up the vision of indefatigable work devoted to the betterment of the lot of mankind, the vision of men who have never sought publicity, of strong personalities whose modesty has always been an inspiration to all who came into contact with them. It is good to know that both are still at work. Every scientific worker will wish to take this opportunity to add to their public honours his tribute to their generous comradeship with the younger generation, their continual output of ideas, assistance and more and yet more results of their own outstanding labours.

Diet of Wood Pigeons

THE recently issued sixth bulletin on wood pigeon studies being organized from the British Trust for Ornithology at Oxford contains some interesting observations of agricultural importance. The examination of nearly 4,000 wood pigeon crops suggests that, contrary to the general belief of farmers, wood pigeons do not eat the 'heart' or buds of clover plants; they eat the leaves and not the buds. Nor do they normally eat young corn but only the seed. During the mild winter of January and February 1943, wild fruits like ivy berries, haws and acorns were found in the 393 crops examined, whereas during the more normal winter of January and February 1942 (131 crops examined) the main food was shown to be cultivated clover. With the co-operation of phenologists a record is being made of the local variations in the abundance of acorn crops, because this seems to be the controlling factor for the movements of the wood pigeon flocks in Great Britain in winter. This might influence forestry work. The food habits of the smaller stock dove are shown to differ. This bird does not take the same food as the wood pigeon: it appears to be more of a ground-feeding species, living almost entirely upon cereals, weed seeds and roots. When the extra acres of woodland are scientifically managed after the War, they may attract the wood pigeon to feed there in the autumn instead of in the farm fields.

Poisonous and Harmful Fishes of Australia

G. P. Whitley has produced a most useful guide to all the poisonous and harmful fishes likely to be encountered in Australia, New Guinea and the islands of the south-west Pacific (Bulletin No. 159, Council for Scientific and Industrial Research. Commonwealth of Australia. Division of Fisheries, Report No. 10, 1943). This work will be useful to members of the Allied Forces who may be unfamiliar with the fishes of these regions, many of which, although attractive in appearance, are very poisonous if eaten, while others possess spines in connexion with poison glands which, if encountered, may cause great pain. The report is well illustrated by coloured and uncoloured figures, and the descriptions are written in non-technical language. Simple methods of treatment for food poisoning and for wounds from venomous fishes are included, and there are also hints for collectors who may wish to preserve specimens. A more detailed and technical work with full bibliography on the same subject is to be published shortly.

Mediterranean Culture

In his Fraser Lecture under this title (Cambridge: At the University Press. Pp. 52. 2*s.* net) Sir John Myres deals with a culture which developed in "an exceptional human habitat". He analyses first the permanent features of the mode of life of the ordinary dwellers in this Mediterranean area. Here is a peasantry closely adapting itself to the possibilities which the environment offered, and a wider community drawing from outside, since "in a region so physically uniform it was necessary to go far for anything unusual". Hence the significance of the sea, and with it sea-power shown legitimately in commerce, colonization, and pilgrimage, and otherwise in piracy. Hence, too, the gulf between the city, product of this sea-life, and the peasantry, a gulf that "has become an enduring fact of Mediterranean life"; and on all, immigrants have made their influence felt. Sometimes they have been "transformed by transit through the mountain zone", sometimes they have disorganized life for a time, but only for a time, since "the primary economic groups persist or re-appear". This summary analysis, to quote the author, "if not quite historical geography is offered as an essay in geographical history". Many will derive pleasure and profit from what is thus offered.

Inter-Allied Charter of Health

The Anglo-Czechoslovak Founders Committee is offering a series of prizes for the best essays on an Inter-Allied Charter of Health. The subjects for consideration in the essays are: (1) the study and survey of post-war relief schemes and other measures for health planning; and (2) the draft of a project to implement Article 6 of the Atlantic Charter with reference to health. A competitor may deal with these subjects separately or jointly. The competition is open to all medical men, public health experts, biologists and other workers in services connected with health. The minimum prize will be £30, the maximum to be determined later. The final date of entry is December 31. The Council for Education in World Citizenship, in collaboration with the Anglo-Czechoslovak Founders' Committee, proposes instituting a parallel competition in British and Allied schools in Great Britain. Further information can be obtained from the Health Charter Study Group, c/o Czechoslovak Institute, 18 Grosvenor Place, S.W.1.

Royal Society of Edinburgh: New Officers

At the annual meeting of the Royal Society Edinburgh held on October 25, the following offic were elected: *President,* Prof. E. T. Whittake *Vice-Presidents,* Dr. James Watt, Prof. T. H. Milr Sir John Boyd Orr, Dr. A. W. Greenwood, Prof. Hindle, Dr. D. Russell; *General Secretary,* Pr James P. Kendall; *Secretaries to Ordinary Meetin* Prof. R. J. D. Graham, Prof. W. M. H. Greave *Treasurer,* Sir Ernest Maclagan Wedderburn; *Cu tor of Library and Museum,* Dr. John E. Mackenzi *Councillors,* Dr. Robert Campbell, The Right H Lord Cooper, Prof. E. W. H. Cruickshank, Sir Donald Pollock, Mr. Stanley Cursiter, Dr. Doug Guthrie, Prof. J. W. Heslop Harrison, Mr. Andrew Young, Prof. E. T. Copson, Lieut.-Col. W. F. Harv Prof. A. E. Trueman, Prof. John Walton.

Announcements

The following doctorates of the University London have been conferred: *D.Sc.:* Mr. B. Ka of University College; Mr. H. G. Wells, an exter student; *D.Sc.(Eng.):* Mr. G. Hughes, an exter student; Prof. A. F. C. Pollard, University profes of (mechanical) instrument design, Imperial Coll of Science and Technology; *D.Sc.(Econ.):* R. G. D. Allen, University reader in statisti London School of Economics.

A discussion on "The Tetrapyrrolic Pigment will be held by the Biochemical Society on Novem 13, beginning at 11 a.m. The meeting will be h in the Department of Organic Chemistry, Imper College of Science and Technology, London, S.W Further particulars can be obtained from Dr. Robson, King's College, Strand, London, W.C.2.

The *Pharmaceutical Journal* has issued a pamph entitled "A Glossary of Terms used in Sex Hormo Therapy". The introduction explains that most the human hormones, excepting adrenalin, are eit proteins, protein derivatives or steroids, and a br description of the nomenclature of the steroids given. The Glossary will be useful to those w cannot make a special study of this field of wo and who have little time to find a way through t maze of names in hormone literature.

Manufacturers of insulin, in consultation w the Diabetic Association, have decided to standard the colour and style of the packings, so that in futu type and strength will be uniform irrespective maker. Steps have also been taken to elimin unnecessary deterioration in pancreas during tran from cold storage to manufacturing plant. T number of diabetics in Great Britain shows a yea increase, and is now estimated at 200,000, but th do not all take insulin. The Ministry of Supply sta that adequate supplies of insulin have been ensu both for the home market and for liberated countri

A million dollars has been set aside by the Cou for the Promotion of Science and Technology China as cash awards for solutions of natio defence scientific problems. The Council for Promotion of Science and Technology has selec ten special industrial and scientific problems consideration. Chinese men of science, industr technicians and research workers are invited engage in studies and research on these problems a submit reports of their results to the Council bef the end of the current year.

Localization of Chemoreceptivity in Drosophila

The outbreak of war brought to a standstill a programme of experimental investigations into the genetics of behaviour patterns among Drosophila mutants in the laboratory of the senior author of this note. The end in view was threefold : (*a*) to take advantage of structural modifications of putative receptor organs by mutation as a basis for exploring their functions ; (*b*) to gain knowledge of reproductive behaviour requisite to further investigation of assortative mating ; (*c*) to standardize the genetic variables affecting behaviour patterns as a basis for inquiries of either type. Recently it has been possible to make a fresh start. The object of this preliminary note is to indicate some positive conclusions about the localization of chemoreceptivity by study of the reactions of mutants with antenna defects or abnormalities, more especially *antennaless*, discovered by Gordon and Sang[1], and *aristapedia*.

The characteristic of the latter is replacement of a normal antenna by a leg-like appendage which, however, bears peg-like organs and other structures of supposedly receptive function present in normal antennæ but not in the normal leg. Full exhibition of the gene *antennaless* leads to complete suppression of both antennæ, partial exhibition to unilateral suppression. By varying the conditions of culture, Gordon and Sang[1] showed how it is possible to obtain genotypically homozygous antennaless individuals with no manifest somatic effect of the gene. Among flies of pure stocks we may therefore distinguish between what they respectively call *antennaless* (A_0) phenotypes, half antennaless (A_1) with unilateral exhibition and wild type antennaless (A_2), the latter being genotypically equivalent to the first two but phenotypically like ordinary flies. It is therefore possible to use as controls flies without antennæ genotypically identical with flies which have them on one side or both sides. Our experiments with these tocks include tests on their phototactic and geotactic eactions, their behaviour in a humidity gradient and heir response to solutions containing volatile contituents. This note deals only with results of the ast-named class.

As is well known, yeast culture and solutions containing ethyl alcohol acetic acid and various esters exert attraction for *Drosophila melanogaster*. A mixture ('M') containing baker's yeast, ethyl alcohol and traces of acetaldehyde, ethyl acetate, methyl acetate and butyric acid attract the flies more strongly than any single constituent. For that reason we have used it for trapping experiments essentially like those of Barrows[2]. The method was to release large numbers of flies in a chamber with traps containing M or water ('W') as a control. Results of a ypical experiment with antennaless stocks are in Table 1, showing the number of flies trapped as a percentage of the number of a given category released. O_r stands for wild type flies of Oregon stock.

TABLE 1.

Solution	Percentage of flies of each class trapped				Total of each group released
	A_0	A_1	A_2	O_r	
M	1	31·5	52·5	58·7	400
W	3	8	5	6·7	

TABLE 2.

	A_0—V_g	A_1—V_g	A_2—V_g	
M	4·5	46·4	98·2	112
W	0·0	1·0	0·0	

TABLE 3.

	SS^a	Y-V-F	F_t	
M	43·6	61·9	70·0	360
W	3·3	3·6	1·9	

Experiments with various mutants having structural defects of the wings leading to defective power f flight conclusively exclude the possibilities that the negative chemoreactivity of the antennaless (A_0) flies is not due to mechanical inability to reach the goal. From this point of view, experiments (Table 2) involving flies ($A-V_g$) homozygous for both the vestigial gene and for antennaless are sufficiently explicit.

A comparison between the behaviour (Table 3) of mutants, for example, *yellow-vermilion-fork* and *filamentless* (F_t) with normal antennæ and *aristapedia* (SS^a) shows that the macroscopic modification of the antennæ in flies of the last-named type does not eliminate chemoreceptivity, though diminishing it somewhat. The characteristic of the *filamentless* mutant control is absence of filaments ordinarily attached to the egg-case.

We have tested the main conclusions illustrated by such experiments with a new type of olfactometer to be described in a forthcoming publication. This device eliminates air flow, offering flies the choice between an exit leading to a chamber containing the attractive mixture and a control chamber with water. The results substantially confirm those of trapping released flies; but also show that total absence of antennæ does not *entirely* abolish receptivity to vapours.

Since microscopic examination of the leg-like antenna of *aristapedia* reveals the presence of the type of sensilla in the distal joint of the normal antenna, our results point to the conclusion that these organs are the chief olfactory receptors involved in the search for food. However, the peg-like organs of *aristapedia* are not the only morphological differentiæ which they share with a normal antenna in contradistinction to a normal leg ; and we are at present investigating the possibility of a more precise identification of the relevant structures by recourse to study of other mutants. Meantime, we have clear-cut evidence that olfactory receptivity of Drosophila, at least with respect to its as yet known chemoreactions, is located almost exclusively in the antennæ.

We acknowledge with appreciation financial assistance from the Rockefeller Foundation for renewal of work on these problems.

Trypan Blue and Cell Migration in the Adrenal Cortex of Rats

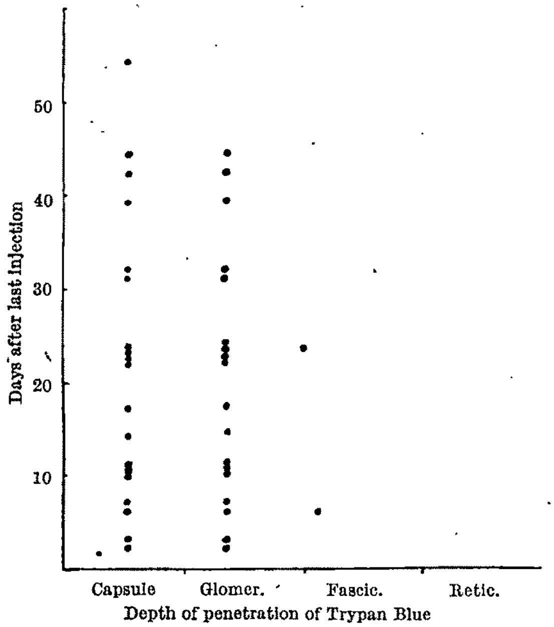
THE hypothesis has recently been put forward that there is an inward cell migration in the adrenal cortex. According to Zwemer *et al.*[1,2], in several species capsular cells multiply and move inwards, becoming in turn cells of the glomerular, fascicular and reticular layers. In guinea pigs Blumenthal[3] found that there is a zone of mitotic activity comprising the inner glomerular and outer fascicular layers, and Hoerr[4] found after chloroform narcosis increased mitotic activity in the outer fascicular layer.

Recently, Salmon and Zwemer[5] claimed that in rats Trypan Blue injected subcutaneously was first taken up by fibroblast-like cells in the capsule, and that afterwards dry droplets were to be found at varying intervals of time in the glomerular, fascicular and reticular zones successively, while the outer layers ultimately became free from the dye. On the basis of these findings they concluded that there was a progressive inward cell migration.

In the hope that this method might provide a reliable technique for the standardization of substances acting upon the cortex, we carried out similar experiments on seven batches, each of six male rats, some of the batches being composed of immature animals. The Trypan Blue was injected in doses of 1–3 c.c. of a 1 per cent solution in saline. The rats were killed 2–54 days after the last injection. Both glands were removed, and stained and unstained sections were examined.

In all sections examined, Trypan Blue droplets were present in the capsule, independent of the lapse of time after injection and the dosage given. Trypan Blue was also found frequently in the glomerular zone and very occasionally in the outer fascicular layer; but the depth of penetration of the dye bore no relation whatever, either to the time interval after the last injection, or to the dose given. The results obtained are plotted on the accompanying chart.

This method thus yields no evidence for centripetal cell migration in the adrenal cortex. The Trypan Blue uptake of the cells of the deeper fascicular and the reticular layers observed by Salmon and Zwemer may perhaps be due to the massive doses used (21–30 c.c. of a 1 per cent solution), which resulted in a generalized absorption of the dye by the whole cortex. It seems possible that the uptake of Trypan Blue and its subsequent appearance in droplet form in the fibroblast-like and glomerular cells is due to the macrophagic activity of the former and to some metabolic peculiarity of the latter, not normally possessed by the cells of the fascicular and reticular zones.



We would like to thank Prof. Samson Wright and Dr. J. H. Woodger for their interest and criticism.

Amount of Heterochromatin as a Specific Character

ONE general fact which emerges from recent work in animal cytology is that the extent of the heterochromatic ('inert') segments of the chromosomes often varies very greatly from one species to another, even within the same genus. Thus, among the grasshoppers, *Stauroderus scalaris* possesses very large proximal heterochromatic regions in all the chromosomes, while in other species of the genus these regions are very much shorter and less conspicuous[1]. The same difference has long been known to exist between species of Drosophila, where *D. virilis* has the proximal half of each autosome heterochromatic, while in some other species such as *busckii* there is far less heterochromatin. These species belong to different subgenera; but it has recently been shown by Wharton[2] that *D. melanopalpa* has considerably more heterochromatin than the very closely related *repleta*. In the Pentatomids, Schrader[3] has shown that *Edessa irrorata* has prominent heterochromatic blocks at the ends of most or all of its chromosomes, which are not obvious in several other members o the same genus. An identical situation occurs in the Corixidæ, where Slack[4] has shown that *Corixa punctata* is a species with unusually extensive heterochromatin.

Since this phenomenon is clearly one of very widespread occurrence in animals (and possibly in plants as well) it seems desirable to have words to designate species with more or less than the average amoun of heterochromatin for the group to which they belong. I should like to suggest that species lik *Stauroderus scalaris, Edessa irrorata, Drosophila virili* and *D. melanopalpa* be called 'megaheterochromatic' the species with little heterochromatin being referre to as 'microheterochromatic'. It is unfortunately no always easy to distinguish between species in which the heterochromatic regions are long and those i which they are of average length but unusuall strongly heteropycnotic at certain stages of th nuclear cycle. It is believed, however, that all th examples cited do actually represent cases where th heterochromatic segments are unusually long, a though they may also be more strongly heteropycnoti than usual.

Heterochromatin, in all those forms where i functions have been analysed genetically, seems to be relatively, but not entirely, inert. That is to say, a heterochromatic region of a chromosome has fewer genes per unit length (as measured at mitosis) and these genes seem to be mostly ones the phenotypic effects of which are individually slight. Duplications or deficiencies of heterochromatic regions are likely to affect the viability of the organism much less than duplications or deficiencies of comparable length in the euchromatic segments. Thus the amount of heterochromatin may be expected to vary more from species to species than the length of the euchromatic segments. But this variation is clearly not haphazard and without significance, since in the megaheterochromatic species the increase of the heterochromatic regions usually seems to have taken place in a very egular and orderly manner in all the chromosomes. Heterochromatin seems to be an invariable constituent of every chromosome, that is to say, all chromosomes contain one or more heterochromatic segments, which may be long or short.

We unfortunately know very little as yet about he role of heterochromatin in the physiology of the cell ; but it is certainly bound up in an intimate way with the whole nucleic acid and protein-synthesis cycle. It is thus quite likely that general differences of a physiological nature may exist between megaheterochromatic and microheterochromatic species. The latter have seldom been studied in detail by cytologists, since it is the presence of conspicuous heterochromatic blocks (rather than their absence) which has attracted attention. Most of the authors ited above who have studied megaheterochromatic species were primarily interested in the phenomenon of non-homologous 'pairing' between the heterohromatic segments, that is, the fact that the ends of the chromosomes are stuck together at certain stages of mitosis and meiosis to form 'chromocentral' ssociations. This seems, however, to be merely incidental to the megaheterochromatic state.

It may be worth pointing out that a comparison between resting somatic nuclei from the same kind of tissue in a number of related species is usually quite sufficient to determine the amount of heterochromatin in a rough manner : in the megaheterochromtic species the chromocentral masses will be very much larger. Eventually, perhaps, we shall have some kind of quantitative index to express the mount of heterochromatin in a species ; at the moment all that seems necessary is a pair of terms to describe the extreme members of what is really a long series. Where heterochromatic supernumerary chromosomes are present in varying numbers in a species (as in the case of the B-chromosomes of maize nd the supernumerary X's of the bed bug[5,6]), this series exists within the species, so that we can distinguish between megaheterochromatic and microheterochromatic individuals. This is clearly an nusual situation, but an investigation designed to detect slight physiological differences between these individuals might throw considerable light on the more general problem of interspecific differences in the amount of heterochromatin present.

Aqueous Soap Solutions of Carcinogenic Hydrocarbons

THE fact that carcinogenic hydrocarbons are insoluble in water has limited the means of administering them experimentally to the use of oily solutions or colloidal suspensions. In feeding experiments, it is a practical advantage to be able to administer substances dissolved in drinking water. Lorenz and Stewart[1] have used hydrocarbons dissolved in stable oil-in-water emulsions. Their method was adopted in some experiments in this laboratory. Where it is desired to achieve rapid absorption of a carcinogenic hydrocarbon from a mucous membrane or from the site of parenteral injection, an aqueous solution has obvious advantages.

Use was made of the mutual miscibility of ether soap and water to prepare aqueous soap solutions of several carcinogenic hydrocarbons. The following method was found to give good results : Up to 120 mgm. of 20-methylcholanthrene or 3 : 4-benzpyrene are dissolved in 10 c.c. of ether, and this solution is added to 50 c.c. of ethereal soap solution. This is the stock solution. Immediately before use, the stock solution is slowly mixed with as much water as is necessary to obtain the desired percentage of hydrocarbon and of soap. The ether is driven off by heating to boiling point. 1 c.c. of the ethereal soap solution used contains 1·8 gm. soap. To obtain a 0·01 per cent solution of hydrocarbon, 6 c.c. of stock solution is mixed with 120 c.c. of water, the percentage of soap being 7·5 per cent by weight. This strength has been used in practice. Fluorescence spectroscopy reveals identical bands for 3 : 4-benzpyrene in aqueous soap solution and in acetone.

After dilution with water, the hydrocarbon solution is at first quite clear, but opalescence gradually develops in the course of a few hours. Even so, the particles are much smaller than those of colloidal suspensions.

Rats show no aversion to drinking 0·01 per cent hydrocarbons in 7·5 per cent aqueous soap solution, and have showed no toxic effects after drinking it daily for six weeks.

After intravenous injection of such aqueous soap solution of 3 : 4-benzpyrene into mice, biliary excretion occurred in the same way as after similar injections of colloidal suspensions[2].

Regulated Degradation of 1,3 Polysaccharides

IT has been shown[1] that when 1,4 polysaccharides, such as starch or cellulose, are treated with periodic acid solution, the carbon chain in each sugar unit is ruptured between carbon atoms 2 and 3, the —CHOH groups at these positions being oxidized to —CHO. Acid hydrolysis of these oxidized polysaccharides yields solutions containing glyoxal and erythrose. It has now been shown in this laboratory that aqueous solutions of periodic acid-oxidized starch or cellulose yield, when treated with phenylhydrazine acetate, a yellow amorphous precipitate. When the mixture is heated on the water-bath, glyoxalosazone is rapidly formed in crystalline condition. The glycosidic linkage, which is fairly resistant to acid hydrolysis, is thus readily opened by the phenylhydrazine reagent under mild conditions.

The interest of this reaction lies in the fact that it may be used to bring about a regulated degradation of 1,3 polysaccharides such as laminarin and the glucan of yeast membrane. It has been shown[2,3] that periodic acid oxidation of these polysaccharides affects only the non-reducing terminal sugar unit, by eliminating carbon atom 3 and oxidizing the $-CHOH$ groups at positions 2 and 4 to $-CHO$. Treatment of the oxidized polysaccharide with phenylhydrazine acetate brings about a rapid separation of glyoxalosazone, and the polysaccharide, the chain-length of which is now shorter by one glucose unit, may be readily recovered. The new terminal non-reducing unit may again be oxidized by periodic acid, and glyoxalosazone again eliminated on treatment with the phenylhydrazine reagent. In this way, the sugar units may be eliminated one by one from the non-reducing end of the polysaccharide chain.

The course of this degradative mechanism may be checked at intervals by oxidizing the $-CHO$ groups in the terminal unit to $-COOH$. The dicarboxylated end-group may then be assayed by neutralization (Barry[2]). The application of this method to yeast glucan, laminarin and other algal polysaccharides of the 1,3 type is at present being investigated in this laboratory. So far the degradation seems to be proceeding as outlined above, although in the case of the yeast glucan, there is evidence that it is halted after ten successive removals of glyoxalosazone. If this should be confirmed by repeated experiments, the failure to degrade the molecule further could be explained on the basis that one or more side-chains had been eliminated, leaving a closed loop of glucose units which now presents no point of attack to the periodic acid.

The reaction should also prove of value in detecting linkages other than those of the 1,3 variety in polysaccharides where the 1,3 linkage predominates. Where, for example, a 1,4 linkage is present, oxidation and subsequent treatment with the phenylhydrazine reagent should bring about a fragmentation of the polysaccharide chain with the production of oligosaccharides of shorter chain-length.

Mid-dorsal Hair Whorls in Papuan Children

THE occurrence of hair whorls in the mid-dorsal region of man has been recorded in a high percentage of Australian aborigines[1,2], in a few Hawaiian fœtuses of mixed ancestry[3] and in one European[4]. Osman-Hill has observed the same anomaly in Veddahs[5].

During a spleen survey of native children in the village of Buna, in northern Papua, the dorsal hair whorl was observed in six out of eighteen children examined. In all cases the whorl was anti-clockwise in direction and centred over vertebral spines *D*4, *D*5, *D*7, *D*10 (each once) and *D*6 (twice).

The significance of this type of hair tract arrangement is obscure; its occurrence in this group of Papuan villagers extends its known range.

Afterglow in High-Pressure Gaseous Discharges

THE persistence of luminosity after the interruption of an electrical discharge in certain gases at low pressures has often been observed, and the experiments on active nitrogen by Lord Rayleigh, and others[1,2], are well known. Dorgelo and Washington[3] have measured the persistence of metastable states in helium, neon and argon; Kenty[4], and Mohler[5], have studied the effect of electronic recombination in the afterglow.

The present experiments differ from those mentioned above in that newer methods of observation and high-pressure spark discharges are used. The results are of some practical interest in the field of high-speed photography.

Recurrent condensed spark discharges were used and the current/time relation for the discharges was accurately determined by means of a cathode-ray oscillograph. In all cases where the afterglow was more than about 5 microsec., the discharge current fell to a negligible value before the glow was extinguished. While it was difficult to prevent a very small current from flowing during the afterglow, such a current is clearly not the sole factor controlling the afterglows, which vary widely from gas to gas. The current/time relation is little affected by a change of gas for the same circuit conditions.

Figs. 1 and 2 are photographs taken with a rotating mirror camera; the time-scale is given with the figures. The hydrogen sparks, three of which are shown in Fig. 1, show no appreciable afterglow compared with argon (Fig. 2), although the spark channel, as would be expected, is wider and more sharply defined in hydrogen than in other gases. The rotating-mirror photographs for hydrogen could not be distinguished from stationary mirror photographs of similar sparks. Owing to the intense afterglow, and lack of boundary definition, the spark channel cannot be clearly distinguished in the argon discharge of Fig. 2.

The argon afterglow varies widely for different sparks in given circuit conditions. The records show that the afterglow is either uniform and wedge-shaped on the photographs, showing a greater persistence of illumination in the centre of the gap or is composed of a number of more or less separate luminous regions, of which at least four are shown in Fig. 2. It would appear, therefore, that the amount of light in the afterglow varies considerably from spark to spark, especially in the later stages of the discharge. A similar effect is obtained for long spark in air, as shown in the rotating-film camera record of Allibone and Meek[6], where again the persistence o exceptionally long afterglows at certain points in th discharge is apparent.

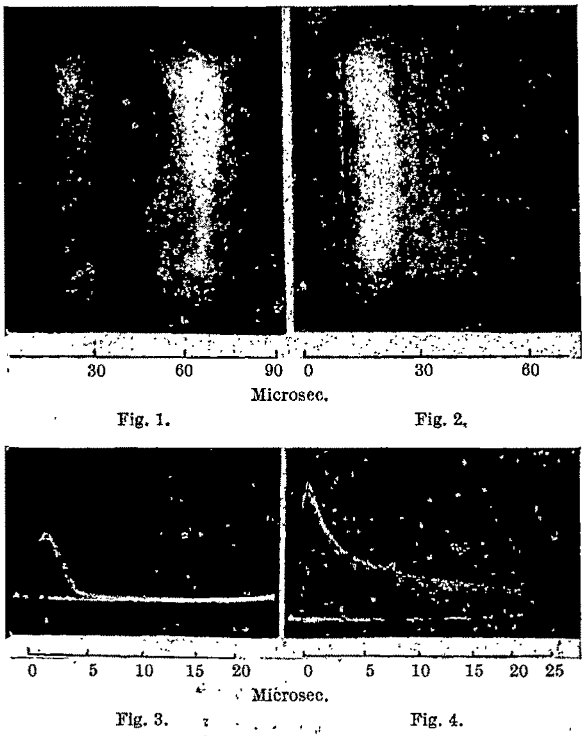

Fig. 1. Fig. 2.

Fig. 3. Fig. 4.

Discharges across point/point gaps (tungsten electrodes 1/16 in. diameter, with hemispherical ends) in 99·5 per cent hydrogen (0·5 per cent oxygen), Figs. 1 and 3: and in 98 per cent argon (2 per cent nitrogen), Figs. 2 and 4.

Fig.	Pressure (atmospheres)	Gap length (cm.)	Capacitance (mfd.)	Approx. circuit resistance (ohms)	Condenser voltage (kV.)
1	1·5	1·0	0·04	13	12·5
2	1·5	1·0	0·04	13	9
3	1·0	0·5	0·02	39	14·6
4	1·0	0·5	0·02	39	14·6

An electron multiplier was used to convert the light pulses from the spark into electrical pulses. Recurrent spark discharges were used, with the spark and the oscillograph time sweep triggered synchronously. The variable nature of the afterglow in argon is borne out in the oscillogram of Fig. 4, which shows the light output from some thousand sparks as a function of time. The intensity of light emitted in the early stages of the discharge is roughly the same for each spark, but there is considerable variation during the later stages. Fig. 3 is a comparable record of the light emitted by many sparks in hydrogen. In this case there is no observable difference in the light/time relation for the separate sparks. The results obtained with the electron multiplier therefore confirm the rotating-mirror records. The effect should be considerably enhanced by the use of a slit, arranged perpendicular to the spark channel. The amount of light passing through the slit to the electron-multiplier would probably then vary much more than the total amount of light for different sparks. It is, of course, the latter quantity that is measured in the experiments discussed above (Fig. 4).

After the electron-multiplier arrangement was devised, similar results with low pressure glow discharges in nitrogen were published[6] and brief references to the study of luminescence in solids, also using an electron-multiplier, have been found[7,8].

As both the electron-multiplier and the spark gap were enclosed in glass bulbs, little ultra-violet radiation from the sparks is recorded. However, the present results are intended only to show qualitatively the nature of the phenomena. In particular, it is important to check, more fully than has yet been possible, the response of the multiplier tube. Also it is hoped that, as circumstances permit, the work will be increased in accuracy and extended in scope to include measurements on the relative and absolute quantity of light emitted by spark discharges in various gases. The use of filters to study light of different wave-length ranges is also contemplated. It is hoped that detailed publications will appear in the future.

Another possible application of the technique, using an electron multiplier and an oscillograph, is the study of the development of the leader strokes which precede spark discharges. The time interval between the leader stroke and the main return stroke might be observed at different points in the gap with a higher degree of resolution than is possible with the rotating camera, where in some cases there is difficulty in distinguishing the leader stroke on account of the relative intensity of the main stroke if the camera speed is insufficiently high. Also, in rotating camera photographs the spatial width of the discharge can confuse the determination of the time relationship, and introduce appreciable inaccuracies even in cases where the camera speed is high enough to separate clearly the leader from the main stroke.

We wish to thank Dr. A. P. M. Fleming, director and manager of Research and Education Departments, Metropolitan-Vickers Electrical Co., Ltd., for permission to publish this note.

Rugosity of Granular Solids

Now that the specific surface of a powder or granular solid can be quickly measured by the air-permeability method of Lea and Nurse[1] or by Rigden's simplification of the method[2], it has become possible for the first time to measure the average roughness and angularity, or 'rugosity' as we may call it, of the individual grains.

Rugosity we define as the ratio of the measured specific surface to the hypothetical surface area which the grains would have if they were all spherical. Wadell[3] recognized the value of this ratio or rather of its reciprocal, sphericity, but was unable to avoid a time-consuming method of measuring the dimensions of many individual grains.

Calculation of rugosity by the present more rapid method is based upon the determination of the specific surface and the particle size distribution. The first of these we measure by the air-permeability method of Lea and Nurse, the cell being modified for coarser particles into a longer and narrower tube; the second is measured by means of an accurately calibrated set of sieves, preferably in a mechanical sieving machine.

The coefficient of rugosity is expressed by the formula:

$$\frac{S_w}{\Sigma a_i . \pi d_i^2},$$

where S_w is the measured surface area of 1 gm. of material in C.G.S. units, a_i is the number of particles having a diameter d_i in the same mass (dimension $[M^{-1}]$), πd_i^2 is the surface of the hypothetical sphere made out of each particle, and the sum Σ represents the total surface of 1 gm. of this idealized material. Using the value w_i, the proportion of the mass in the i^{th} sieve fraction (dimensionless), we can write:

$$w_i = a_i \tfrac{1}{6} \pi d_i^3 \rho,$$

where ρ is the density of the material. We can also calculate a_i, which is:

$$a_i = \frac{6 w_i}{\pi d_i^3 \rho};$$

and from this we arrive at the coefficient of rugosity:

$$\frac{S_w \rho}{6 \Sigma (w_i/d_i)},$$

which is dimensionless.

It should be noted that a_i, used in the intermediate calculation, does not represent the actual number of irregularly-shaped particles, but the number of spheres that can be made out of each fraction keeping the experimentally determinable w_i and d_i correct.

An improvement can be made in the accuracy of the results if, instead of the actual sieve analysis figures, closer values are read from a frequency curve, which can be prepared by the graphical differentiation of the cumulative curve. Sieve sizes should be chosen so that not too high a proportion of the whole sample finally rests between two sieves.

The new method was developed in the course of work on the properties of synthetic steel moulding sands. It was found that two sands having the same specific surface, when mixed in the same way with the same proportion of water and 'Fulbond', a bonding material produced from fullers' earth, behaved quite differently in the green compression strength and plasticity tests. Microscopical examination showed that the grains of one of the sands were larger, rougher and more angular than those of the other.

The coefficients of rugosity of these silica sands are usually between 1·05 and 1·40, approaching unity when the grains are well rounded. The method is being applied by the Department of Refractory Materials, University of Sheffield, in the study of silica sands for use in synthetic moulding and core sands being conducted in conjunction with the Moulding Materials Sub-committee of the Iron and Steel Institute's Steel Castings Research Committee, and has yielded information of considerable value.

Coefficients of rugosity are likely to be valuable in the study of the flow properties of dry powders, and of the rheological properties of insoluble powder – liquid systems. It is a useful measurement for evaluating substances which are required to have a high specific surface combined with a high permeability to fluids, such as fullers' earth and base exchange materials. The method can probably be used for estimating the degree of aggregation of particles the separate particle size of which can be otherwise determined. So far the measurement has not been extended to particles which are platy or acicular, but a correction for particle shape could probably be made in the sieve analysis as suggested by Rittenhouse[4].

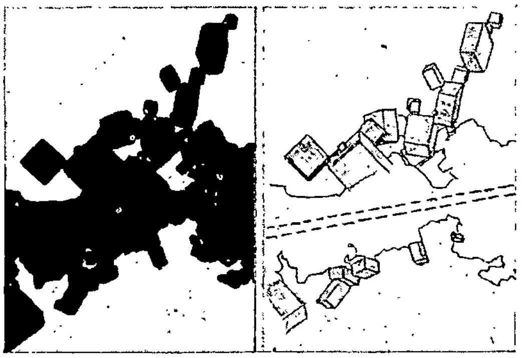
Electron Microscope Studies of the Capture of Air-borne Particles by Single Fibres

IN the course of some work with the electron microscope, studies have been made on the capture of small air-borne particles by single fine fibres.

In the accompanying illustration, *a* is the electron microscope picture (× 1900) of a collection of fine sodium chloride crystals clinging to a fine rubber fibre. Sodium chloride solution had been sprayed with an atomizer into air which was drawn past the fine fibre. The dotted line in *b* indicates the size of the fibre, which was approximately 0·7 mμ in diameter.



a *b*

The negative from which this print was made was projected on a wall screen so as to give an image considerably larger than the accompanying figure, and the apparent boundaries of the individual crystals were sketched on the screen; *b* is a photograph[1] of the resulting drawing, and gives a very interesting picture of the way crystals are caught and packed together.

This work was carried out in the course of experiments done by Dr. Beatrice Deacon, Dr. L. T. Newman and Dr. J. H. L. Watson; this particular experiment was done by the last-named.

AN INTERNATIONAL INFORMATION COUNCIL[*]

By PROF. A. F. C. POLLARD

Imperial College of Science and Technology

VALUABLE information on a subject is frequently scattered outside the recognized field of that subject and may appear in unexpected types of literature, as illustrated by the classical example of Mendel's two papers on his famous laws governing the inheritance of characters in plants and animals, which lay in obscurity for thirty years, and the remarkable French patent specification of Penaud and Gauchot of 1876 describing the modern aeroplane in detail, which was not brought to light before 1916.

Extensive search is necessary to gather all the available information on any subject, and the magnitude of the searching and sifting process is beyond the capacity of individual information services. Moreover, most services entirely neglect certain kinds of literature, such as university theses, patent specifications and trade literature, all of which are essential material for particular groups of people. Some services, however, recognize the importance of such literature. The Mellon Institute and the Carnegie library at Pittsburg, for example, have formed large collections of trade literature indexed by subject and name of firm.

The vast task of indexing the current literature alone could only be carried out by a carefully planned international organization by which the contents of all non-fiction literature were analysed, classified and recorded in the form of a simple bibliographical reference, as distinguished from a compound reference in which the simple reference is compounded with notes or an abstract. For the smooth working of the plan to be described, it is essential that these simple bibliographical references should be subject-classified by a standard international code, such as that known as the Universal Decimal Classification now in course of publication as a British Standard by the British Standards Institution, and prepared in a standard form which will shortly be published by the same body.

Bibliography is the work of specially qualified people. Usually the research worker, in whatever domain of learning he may work, is not qualified for bibliographical research, and in any event is denied the facilities open to the professional bibliographer. The intrusion of such work into his otherwise occupied time is resented, and in consequence his references are fragmentary and exert an undesirable influence upon the quality of his output. It was necessary to organize groups of specially qualified persons to analyse and classify man's priceless inheritance of recorded knowledge in order to make full use of it for the benefit of mankind.

In the international organization proposed, a supreme body, the International Information Council, is linked to national information committees situated in the literature-producing countries of the world, and under each national committee a family of national information bureaux carry out the work of recording the contents of the national literature. The essential feature of the plan is that the national information organization of a country shall deal exclusively with the literature produced in that country.

The organization is intended to serve government departments as well as the public, and the bodies composing it should be governmental or semi-governmental bodies subsidized by government funds. The bureaux under the national information committee of a country would deal with specific domains of the national literature, such as those concerned with general works, science and technology, agriculture, medicine, fine arts, philosophy, theology, sociology and law, commerce, languages, literature, history, etc.

The organization, in fact, is somewhat similar to the system of the Executive Council of the Imperial Agricultural Bureaux, with its twelve sections each concerned with a branch of science bearing on agriculture, which according to the report of the British Commonwealth Science Committee of March 29, 1943, ". . . has since its inception in 1929 been an outstanding success in providing a vital service, collecting, collating, and disseminating information on agricultural research to workers throughout the Empire and the world. The fact that this organization, administered by a constitutional and representative executive council sitting in London, has been continuously supported since 1929 by the whole Empire on the basis of an agreed contribution, surely implies that governments would be sympathetic towards an extension of such a scheme to other essential scientific services".

The personnel of the International Information Council should include representatives of the national information committees, and the personnel of each national information committee should include representatives of its bureaux, which consist of information officers fully qualified to deal with the literature of their respective subjects.

Assuming that the standard methods of preparing simple bibliographical references and the standard classification have been internationally adopted and that the world organization is in operation, current literature would be dealt with in the following manner. A list of the national material, as and when published, is obtained by the national information committee from the national library enjoying the rights of legal tax, or failing that from publishers' catalogues and other sources. The documents are obtained and roughly classed by the standard classification numbers and distributed to the bureaux. If the bureaux are assigned the classification numbers of their subjects, the distribution by means of these 'bureau numbers' becomes automatic. But some of the documents received by a bureau may contain 'unwanted' matter; in this case it is roughly classed and sent to the correct bureau for action. The bureaux prepare the MSS. of the references, which are printed on the international standard card, by the national committee. Copies of the cards are then distributed by the bureaux to their opposite numbers in other countries by means of air transport, in order to reduce the time of distribution to a minimum. It will be noted that in this process of distribution, it is not necessary for analogous bureaux in the different countries to have precisely the same bureau numbers, since it is only the bureau numbers which are the instruments of selection.

In this way each bureau will accumulate those references to the current literature of the world concerning its specific domain of information, and will build up a classified subject, or more correctly an 'ideological' card repertory of simple bibliographical references, which can be filed in duplicate to form an author, title, or generally an 'onomastic' card repertory.

---

[*] Substance of a paper on "A Plan for Mobilizing Bibliographical References to the Contents of the World's Non-Fiction Literature" read at a meeting of the British Society for International Bibliography on September 28.

Non-current literature could be gradually dealt with in the same way by systematic reference to accession lists and union catalogues. The records for the non-current literature of a country would take many years to complete, but it is important that the current literature should be attacked as soon as possible before the growing mass gets beyond human control.

By an extension of the exchanging process to the national committees, a great central repertory of all information could be formed, but the enormous mass of references which would accumulate and the space required for storage would make such a proposition impossible to entertain, even if any advantages could be gained by having such a colossal and central national repertory. Each bureau must necessarily be established at an information centre where the material and the card repertories may be stored for use by the information officers and the public.

The application of this proposed organization to British bibliography might be made in either of two ways. The countries of the Empire may be regarded either in the geographical sense, each with its own national committee and family of bureaux, or the whole British Commonwealth may be grouped under one national committee, which might be called the British Commonwealth Information Committee. With this arrangement the bureaux probably would function as successfully as the twelve branches under the Executive Council of the Imperial Agricultural Bureaux.

Suitable British information centres should be government and public institutions in London, such as the libraries of the Science Museum—for the bureau or bureaux dealing with science and technology—the Victoria and Albert Museum, the Public Record Office and so on. Other libraries and institutions in different parts of the country should be authorized to obtain copies of any desired domains of the official card repertories, so that the records could be dispersed over the country for the benefit of the nation.

The organization is thus fundamentally concerned with the analysis and classification of information in the form of simple bibliographical references. Other services such as abstracts, progress reports, the provision of photo-copy, translation, special bibliographies on demand, loan services, etc., should be regarded as services outside the activities of the official international organization. Many of these services are in vigorous activity and obviously should be improved and developed by the use of the complete records filed in the card repertories of the official organization. It is stated in the report of the British Commonwealth Science Committee, to which reference was made above, that "The case for collaboration in the production of scientific abstracts of high quality for the common use of the English-speaking world is very obvious, and would have the strong support of the Committee". If the major abstracting services would agree to collaborate and adopt a method of passing on 'unwanted' matter to the appropriate service, in a manner similar to that described for material 'unwanted' by the official bureaux, the case might be made. The official card repertories unquestionably would greatly assist the abstracting services and help to avoid duplication more especially if each abstracting service was identified by classification numbers.

This immense international organization with its bureaux all over the world could not, of course, be established in its entirety in the first instance, but there appears to be no reason why the plan should not be initiated by the establishment of an Anglo-Soviet-American organization, primarily concerned with British, Russian and American current literature. The literature of other countries could be divided by agreement among the three members of the United Nations, and the work undertaken for any country in this way could be handed over as soon as its national information committee with the necessary bureaux had been established by the assistance of the International Information Council.

X-RAY ANALYSIS GROUP OF THE INSTITUTE OF PHYSICS

FOR some time past the need has been felt for closer co-operation between the users of X-ray diffraction methods. In industry, for example, many new applications are being found for these methods and their simplicity and directness make them valuable additions to industrial testing procedure Their use may sometimes be entirely empirical, but a sound understanding of the theoretical basis is necessary in order that the practical worker shal both recognize the limitations of his methods and be able to tackle the more unusual problems that are bound occasionally to be presented to him. It is desirable, therefore, that there should be some means for the technician to become acquainted with the latest results of theory, and for academic circles to learn of the problems that X-ray analysis is being called upon to solve.

The need has been partly met by the X-ray Conferences of the Institute of Physics, which were held in Cambridge in 1942 and 1943. Though their support, both from industry and from the universities was evidence of their success, the Board of the Institute has realized that such conferences can be of only limited value, and has now authorized the formation of an X-ray Analysis Group.

Despite its connexion with the Institute of Physics it is not intended that the membership should be confined to physicists. Since the formation of the Group has been sponsored by the Institute, the present committee has a strong bias on the side o physics, but it is hoped that it will become more truly representative of the different branches o science as vacancies in it are filled by election.

The inaugural meeting of the Group was held on Saturday, October 16, in the Physics Departmen of the University of Manchester, at the invitation o the Manchester and District Branch of the Institute Dr. F. C. Toy was in the chair. The papers read illustrated very well the objects for which the Group was formed.

The main lecture was given by the chairman o the Group, Sir Lawrence Bragg, on "The Physical Optics of X-Ray Analysis". Sir Lawrence emphasized the essential similarity between the diffraction o light by a grating and of X-rays by a crystal, and showed how the same principles can be applied to both. He spoke rather regretfully of the tardiness with which the mathematical theory of diffraction has been applied to X-ray problems and said that, now that the theory has been worked out, it is essential that those who use X-ray diffraction methods should make themselves acquainted with it; the 'Bragg Law' does not contain the whole of the subject.

Sir Lawrence then described the fundamentals of the theory of X-ray diffraction and the essential part that Fourier series play in it. He described how one is led to the concept of the 'reciprocal lattice' and explained, by reference to line gratings, how the theory can be used for the study of crystals deformed in different ways. Finally, he showed how appreciation of the similarity of the diffraction of X-rays and light can help in devising practical methods for crystal analysis. He described an apparatus for observing diffraction at small angles, and showed how it can be used for determining directly the intensities of a zone of reflexions given by the projection of any postulated structure. It can also be used for observing the diffraction pattern given by a single molecule or unit of pattern, and there are thus possibilities of working out structures completely by this means. Great advances may be expected when it becomes possible to work out these methods in greater detail.

After an interval for tea and for the inspection of the exhibition that had been arranged, four short papers on industrial applications were read.

Mr. C. W. Bunn, of Imperial Chemical Industries, Ltd., Northwich, showed some cinematograph films of growing crystals. These provide a great deal of evidence of the manner in which crystals are formed, and Mr. Bunn emphasized that there is still no complete explanation of all the phenomena observed.

Dr. A. H. Jay, of the United Steel Companies, Stocksbridge, described some results he has obtained on the correlation of the crystal structure, hardness and magnetic properties of some iron – chromium – nickel alloys. The face-centred cubic structure changes partly to body-centred cubic when the alloy is drawn into wire, and the changes of structure and hardness can be followed across the section of the wire.

Dr. I. MacArthur described the rotating anode X-ray tube in use at the Textile Physics Laboratory, University of Leeds. This tube differs from others in the smallness of the power it uses; the great efficiency is due to the fineness of its focus. That this is an important factor was shown by slides in the lecture and by prints in the exhibition; for example, there were fibre photographs taken with an exposure of less than a minute that would have taken hours with ordinary apparatus (see NATURE, July 10, p. 38).

Finally, Mr. L. D. Brownlee, of the Metropolitan-Vickers Electrical Company, Ltd., Manchester, described the use he has made of X-rays in the study of sintered carbides used for tool-tips. The subject is peculiarly suited to X-ray examination, and the information that has been obtained about the equilibrium diagrams of the components has proved extremely useful in understanding the nature of the reactions involved in the process of manufacture.

A lively discussion of the various papers followed. The interest shown and the attendance of nearly three hundred people at the meeting augur well for the future of the Group and of X-ray analysis in general. Further particulars about the Group can be obtained from Dr. H. Lipson, Crystallographic Laboratory, Free School Lane, Cambridge.

THE FREEDOMS OF SCIENCE

An address on "The Freedoms of Science" was given by Sir Robert Watson-Watt at an open meeting organized by the North-West Area of the Association of Scientific Workers in the Manchester College of Technology on October 18.

Sir Robert said that the demand for more central planning of science comes from people with a passionate sense of social responsibility. This demand has produced fears and fairly widespread opposition, some of which came from distinguished men of science of undoubted sincerity. There is a gap between these points of view, and he believes that it is both narrow and narrowing. The classical definition of science as organized knowledge is confusing, because it suggests a wholly artificial separation between pure science and technology. In Sir Robert's opinion, civilization began in technology, and pure science arose later when technology had made possible the leisure necessary for its pursuit; but to-day the applied scientist uses the same strict criteria of accuracy and logical evaluation as does the pure scientist.

Considering the position in the universities, Sir Robert maintained that pure science is already subject to planning. In addition there is a strong element of industrial planning; industrial undertakings make subventions to university departments. By whatever means a university is financed there is some form of budgetary control, and this control should be planned.

Sir Robert said he had discovered no debate about the need for some measure of planning in the application of science in war-time, but planning in hope for peace is nobler and more productive than planning for war through fear. One of the benefits of technology is to remove drudgery, but unless its application is planned, the result will be unemployment. A large part of scientific effort should be diverted to present needs, but pure science should also receive adequate provision. The facilities which the planners demand for pure science are on a scale which, rather curiously, is vastly greater than the 'freedomists' feel to be necessary. No 'direction' of labour in the scientific world is envisaged. The individual man of science must have the freedom to learn, think, choose, work and speak, but must never claim freedom from self-explanation, external criticism and social responsibility. There is a danger from overplanning, but it is slight. A potential Newton might remain mute and inglorious, submerged in a routine technological process, but that is unlikely to happen.

The kind of planning Sir Robert desired would provide for the free exchange of information. Some very successful planning bodies have been set up during the War, and could be copied in times of peace. The structure should be wholly democratic, and should enable the user to meet the research worker and state his requirements, and the research worker to explain what is and is not practicable. It would be necessary to bring the young bench-worker into the council chamber occasionally for this purpose. The planning of science is obtainable easily, smoothly and productively, and without danger to the freedom of fundamental science.

During the discussion, Prof. M. Polanyi said that, unlike Sir Robert, he believed that pure science should not be confused with technology. The search for organized knowledge, he said, cannot be planned, and it would be disastrous to attempt it. If pure scientists were diverted from their present work to something else, the work they are doing must suffer. If no such diversion is contemplated, it is unnecessary to raise the question of planning. He realized that such diversion is necessary in time of war or great emergency, but we should never lose sight of the implications of such proposals. One speaker suggested that this difficulty could be overcome by training more scientific men.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, November 6

Nutrition Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1).—Conference on "Post-War Nutritional Relief".

Society of Chemical Industry (Glasgow Section) (joint meeting with the Scottish Group of the Nutrition Society) (at the Royal Technical College, 204 George Street, Glasgow), at 2.30 p.m.—Discussion on "Diet in relation to Industrial Health".

London Scientific Film Society (at the Imperial Institute Cinema, Exhibition Road, South Kensington, London, S.W.7), at 5 p.m.—Coal; VIEM; Pavlov Experimental Farm; Neuropsychiatry.

Monday, November 8

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 8 p.m.—Dr. Douglas Guthrie: "Greece and Aegean Islands" (with Kodachrome Films).

Tuesday, November 9

Society of Chemical Industry (Chemical Engineering Group) (joint meeting with the Manchester Section of the Society and the Institution of Chemical Engineers) (at the College of Technology, Sackville Street, Manchester 1), at 2.30 p.m.—Major V. F. Gloag and Mr. R. J. Barritt: "The Manufacture of Sulphuric Acid in Contact Plants".

Institution of Civil Engineers (Railway Engineering Division) (at Great George Street, Westminster, London, S.W.1), at 5 p.m.—Mr. C. E. Fairburn: "The Electrification of the Wirral Lines of the L.M.S. Railway".

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Henry Dale, G.B.E., P.R.S.: "Progress in the Treatment of Infections", 2: "The Beginnings and Growth of Chemotherapy".*

Wednesday, November 10

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 1.45 p.m.—Mr. P. R. Morris: "Education To-day and To-morrow", 1: "English Education As It Is".

Society of Chemical Industry (Food Group, Microbiological Panel) (at the Chemical Society, Burlington House, Piccadilly, London, W.1), at 2 p.m.—Dr. J. Ramsbottom: "Fungi as Food".

Physical Society (Colour Group) (joint meeting with the Technical Section of the Paper Makers' Association of Great Britain and Ireland) (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 2.30 p.m.—Mr. S. R. H. Edge: "Colour Measurement for Control and Research in Paper Making".

Chemical Society (joint meeting with the Glasgow University Alchemists Club and the Andersonian Chemical Society) (in the Chemistry Department, The University, Glasgow), at 3.30 p.m.—Prof. John Read, F.R.S.: "Humour and Humanism in Chemistry".

Royal Meteorological Society (at 49 Cromwell Road, South Kensington, London, S.W.7), at 4.30 p.m.—Papers.

Wednesday, November 10—Thursday, November 11

British Coal Utilisation Research Association (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1).—Conference on "Problems in the Utilisation of Small Coals".*

Wednesday, November 10

At 2.30 p.m.—"The Utilisation of Small Coals and Slurries".

Thursday, November 11

At 10 a.m.—"The Utilisation of Fuels of High Inert Content".
At 2.30 p.m.—"The Upgrading of Fuels".

Thursday, November 11

Chadwick Public Lecture (at the Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1), at 2.30 p.m.—Mr. J. H. Forshaw: "Town Planning and Health" (Bossom Gift Lecture).*

Royal Institution (at 21 Albemarle Street, London, W.1), at 2.30 p.m.—Sir James Jeans, O.M., F.R.S.: "The Methods of Modern Astronomy", 2: "Photographic Astronomy".*

Royal College of Surgeons of England (at Lincoln's Inn Fields, London, W.C.2), at 3.15 p.m.—Mr. H. S. Souttar: "Physics and the Surgeon" (Bradshaw Lecture).

Society of Chemical Industry (Newcastle Section) (joint meeting with the Royal Institute of Chemistry, Chemical Society, and Oil and Colour Chemists Association) (in the Lecture Theatre, King Edward School of Art, King's College, Newcastle-upon-Tyne), at 6 p.m.—Mr. I. W. A. Kirkwood and Dr. P. D. Ritchie: "Plastics"

Pharmaceutical Society (at 17 Bloomsbury Square, London, W.C.1), at 7 p.m.—Mr. M. A. H. Tincker: "The Use of Plant Growth Substances".

Friday, November 12

Royal Entomological Society of London (joint meeting wi the British Ecological Society) (at 41 Queen's Gate, Sou Kensington, London, S.W.7), at 2.30 p.m.—"The Inter-relations Plants and Insects—the Place of Both in the Eco-System" (Speake Prof. E. J. Salisbury, F.R.S., Dr. E. A. Cockayne, Capt. Cyril Div and Dr. C. F. C. Beeson).

Royal Institution (at 21 Albemarle Street, London, W.1), 5 p.m.—Dr. C. D. Darlington, F.R.S.: "The Origin of Cultivat Plants".

Chemical Society (in the Chemistry Lecture Theatre, The Univ sity, Sheffield), at 5.30 p.m.—Prof. N. K. Adam, F.R.S.: "Surfa Films".

Chemical Society (joint meeting with the University Colle of Bangor Chemical Society) (in the Chemistry Lecture Theat of University College, Bangor), at 5.30 p.m.—Prof. M. Polany "The Strength of Carbon Bonds".

Institution of Mechanical Engineers (at Storey's Gate, S James's Park, London, S.W.1), at 5.30 p.m.—Mr. W. E. Ballar "Reclamation of Worn Parts by the Metal Spraying Process"; M W. Andrews: "Building-up and Hard-Surfacing by Welding' Mr. A. W. Hothersall: "The Repair of Worn or Over-machin Parts by Electro-Deposition".

North-East Coast Institution of Engineers and Shipbuilde (at the Mining Institute, Newcastle-upon-Tyne), at 6 p.m.—I T. H. Havelock, F.R.S.: "The Approximate Calculation of Wa Resistance at High Speed"; Dr. J. Lockwood Taylor: "Pressu Distribution on Propellers".

Saturday, November 13

Biochemical Society (in the Department of Organic Chemistr Imperial College of Science and Technology, South Kensington, Lo don, S.W.7), at 11 a.m.—Discussion on "The Tetrapyrrolic Pigments

At 11.15 a.m.—Prof. D. Keilin, F.R.S.: "Properties and Functi of Natural Tetrapyrrolic Compounds".

At 12.10 p.m.—Prof. H. Munro Fox, F.R.S.: "Varieties Hæmoglobin".

At 1.45 p.m.—Mr. R. Hill: "Tetrapyrrolic Compounds in Plants

At 2.35 p.m.—Dr. E. R. Hartree: "The Constitution of Catalase

At 3.15 p.m.—Mr. J. R. P. O'Brien: "The Metabolism of Bloc Tetrapyrrolic Pigments".

At 4.30 p.m.—Dr. C. Rimington: "The Porphyrinopathies".

APPOINTMENTS VACANT

Applications are invited for the following appointments on before the dates mentioned:

Deputy City Surveyor and Engineer—The Town Clerk, Tow Hall, Manchester 2 (endorsed 'Deputy City Surveyor and Enginee (November 10).

Two Science Masters (or Mistresses) to share the teaching Chemistry and Physics in the Wellingborough Grammar School Higher School and Scholarship standard—The Secretary for Educ tion, County Education Offices, Northampton (November 11).

Transport Manager and Engineer—The Town Clerk, Tow Clerk's Office, Tonbridge Road, Maidstone (November 12).

Team Leader for Entomological Work in connexion with schen of the Ministry of Agriculture for Pest Control—Prof. R. G. Whit School of Agriculture, University College of North Wales, Bang (November 12).

Graduate Assistant Master with special responsibility for th Technical Department (a Physicist with ability to teach Mathemati is being sought, and preference will be given to candidates with son knowledge of Engineering and/or Industrial Experience)—The Princ pal, South Dorset Technical College, Newstead Road, Weymout (November 12).

Educational Psychologist (part-time) to undertake work at tl Chislehurst Child Guidance Clinic—The County Medical Office County Hall, Maidstone (November 13).

Lecturer in Physics (graduate with, preferably, high qualific tions in Physics, and able to teach classes in Elementary Mathematic —The Director of Education, The Polytechnic, 309 Regent Stree London, W.1 (November 15).

Lecturer in Mechanical or Production Engineering Subjec up to Higher National Certificate standard in the County Technic College, Wednesbury—The Director (H), County Education Office Stafford (November 15).

Assistant (temporary) in the Department of Geography- The Registrar, The University, Leeds 2 (November 15).

Laboratory Technician (must hold Certificate of Institute Medical Laboratory Technology, or its equivalent, and have co siderable experience in Biochemistry)—The Medical Director "R.2' Staines County Hospital, Ashford, Middlesex (November 18).

Technicians (highly skilled in Bacteriological and Serologic Venereal Disease technique) for a Bacteriological Laboratory—Tl Town Clerk, The Guildhall, Nottingham (November 20).

Professor of Engineering—The Registrar, University Colleg Singleton Park, Swansea (November 20).

Assistant (temporary) to teach Mathematics and other Juni Engineering Subjects—The Principal, County Technical College an School of Art, Newark, Notts. (November 22).

Psychologist (with an Honours Degree in Psychology, experienc of testing, remedial teaching, and preferably child guidance work)- The Medical Superintendent, Central Mental Hospital, near Warwic (December 4).

City Engineer and Surveyor—The Town Clerk, Town Clerk Office, St. Albans (endorsed 'City Engineer') (December 10).

EDUCATIONAL RECONSTRUCTION (6)

SCIENCE AS AN EDUCATIONAL DISCIPLINE

THE recent publication of the White Paper on Educational Reconstruction, the Norwood Committee's Report on the Curriculum and Examinations in Secondary Schools, and the several other reports relating to the same or similar themes, together with the large number of articles already published commenting chiefly on the first two important publications, have raised once again the all-important question of the place that science is to take in future education.

Many of these pronouncements still betray a strange lack of appreciation of what science has to offer, and, indeed, of what science really is. Too many educationists, and, in fact, too many other men of science, still think of it as little more than weighing and measuring, laboratory and test tube. This is reflected in the science syllabuses of most of our schools of to-day—especially secondary. No doubt the ever-present vicious circle inspired by the examination system—school, university, school—is responsible for much of this, and until the whole examination system receives the long overdue drastic revision now so desperately needed, the 'subject' bogy will continue to baulk the efforts of the most ardent and authoritative reformers.

In this respect perhaps the universities are more to blame than the schools. While the former persist in retaining their rigid division into faculties and departments with so little collaboration, exchange of ideas and pooling of effort among themselves, so must we tolerate the present artificial division of our school curricula into 'subjects'. Most of our teachers must inevitably leave the university having graduated in two to four subjects. In these subjects one assumes they are comparatively well read, but outside these subjects one is equally justified in assuming that most of them know little or nothing. During their academic careers, the demands of their own university examination system have made it impossible for them to spare much time for anything but their degree subjects. Then afterwards, the school examination system almost precludes even the most progressive teacher from straying very far beyond the syllabus dictated by the requirements of the examinations.

A proposal is being made by the British Association Committee on Post-War University Education which should go far in helping to remove this serious blemish on our system of training teachers (see NATURE, **150**, 716; 1942), and it is to be hoped that the Board of Education Committee on the Training and Supply of Teachers is taking due note of this. Meanwhile, science in our secondary schools still largely comprises the subjects of physics, chemistry and biology (and in many cases not even the last-named) to the exclusion of all other aspects of science, except, in some cases, in the lower forms.

Furthermore, the attitude of the schools to the above three subjects alone is all too frequently based on traditional beliefs and premises which should have been discarded long ago. For example, it should not have been necessary for the Women's Engineering Society at its recent annual conference to deprecate the fact that in the education of girls insufficient emphasis is laid on the teaching of physics and applied mathematics. The statement is a true one, and the Society's complaint justified. The reason for this complaint coming from such a Society is clear, but its implication is an indictment of our educational system. The fact that girls do not study enough physics and applied mathematics is really a relative one, for which there is neither rhyme nor reason. Through the past several decades girls have studied more of the biological sciences (until recently, botany only) and less of the physical sciences, and the boys vice versa. It is probable that this was due to the very narrow view of science in education then held—namely, utilitarian; in after-life boys would not need biological knowledge and girls would not need physical knowledge. The trend is away from this to-day, but the schools still have a long way to go. Once science is accepted as something more than a vocational discipline, then this false emphasis on certain aspects of science, this baseless differentiation between boys and girls, will disappear once and for all, though certain rational distinctions must be recognized.

There is very little direct reference to science in the White Paper on Educational Reconstruction. This, of course, is to be expected, since the White Paper is not concerned to any great extent with syllabuses, though its proposals will certainly affect them. It is to be hoped, for example, that when the large number of new school buildings are being planned, reasonable scope will be allowed for the demands of science—buildings, laboratories and equipment. This is not asking too much provided a comprehensive, and therefore reasonable, view of science as a school discipline be taken. It does not imply costly equipment, neither does it imply large and expensive laboratories. In fact, even if funds were available, both should be discouraged. To-day, with science teaching organized as it is and with the examination system dominating secondary school education as it does, too much time is spent in laboratory and other practical work. This is probably due to the fact that we still tend too much towards science as a vocational subject. True, the vocational aspect is of outstanding importance and will be even more so in the proposed new technical schools. There the more utilitarian sciences will demand much of the pupil's time, and laboratories and equipment will be very necessary adjuncts to the science teacher.

One feels somewhat discouraged even so far as this is concerned when one realizes the amount of money which the White Paper proposes allocating for the purpose of technical education (see NATURE of November 6, p. 517). The Education Committee of the London County Council has also deplored the lack of provision in the White Paper for a much greater rate of progress in the development of technical education.

But science also has its cultural aspect, and here educationists and educators of the future will have to broaden their views and consider the important aspects of science which are not directly vocational, but have an important part to play in cultural training and training for citizenship. Such aspects of science are, for example, the social implications of science, the history of science, and so forth. Until quite recently, most secondary schools where biology was taught merely gave a brief survey of the plant and animal kingdoms; almost invariably man was excluded. Now the social implications of biology are being more and more emphasized in, for example, health education. The Central Council for Health Education has for some time pressed for biology in schools to be used as a background for health education, and one could with profit go still further, using this so-called 'subject' as a basis for the elementary study of vital statistics, population problems, population movements, and so forth.

The cultural aspect of science will find a greater place in the newly proposed grammar schools and also in adult education. Experience in lecturing to adult audiences (at present chiefly in H.M. Forces) shows that there is a very keen demand for the study of science in so far as it affects man and mankind. This is, of course, in addition to the demand for vocational training. The latter should not take a very high place in the new senior and grammar schools.

All teachers, in schools and universities, bear the responsibility of transmitting the traditions of our civilization, and when science is being taught the teachers cannot help having its obligations in their minds, and those obligations must be taken into account. Science has made, and is still making, exceedingly rapid progress, and the correspondingly rapid accumulation of consequences, with their nature, extent and variety, are causing great concern in the world to-day. All this, however comprehensive it may appear, must be borne in mind by teachers when teaching science.

Social control over science is still an undeniable fact. Prof. J. D. Bernal, in his "Social Function o Science", has given a comprehensive analysis of thi social influence, but science has now acquired a momentum and strength of its own. It is not conten to accept the problems society suggests to it. I also states its problems to society. Science must b recognized as a very powerful social force which ha certain social requirements for which it demand satisfaction. This aspect of science must not b ignored in the schools of the future.

Although there are a utilitarian side and a cultura side to science, there is no distinct boundary betwee the two. Base desires are often associated with, an give an unpleasant sound to, the word 'utilitarian' This is probably due to the fact that many people ar not primarily interested in the investigation of socia life or in the formulation of what the scientifi attitude has to contribute towards it; but if 'utilitarian' means making man of use to himself and t his fellow men, the word is rescued from that unpleasant association. In this sense it covers knowledge c how to treat one's body, how to conduct one's ow business, how to help others, how to make use of the public services, and so forth.

Bearing in mind the conditions under which our children are going to work and live after leaving school, and still keeping to the utilitarian point of view, we must ask ourselves what knowledge of science we can reasonably and profitably give to them. Without attempting too much vocational training, we should try to make pupils receptive, ready to appreciate what is told them in the name of research, and to respond to advice. The cultural side refers to the effects of science on the minds of children and of the men and women they will become. This is emphasized in the Report on the Teaching of General Science prepared by the Science Masters' Association: "Of all the claims made for the inclusion of science in a school curriculum, the strongest undoubtedly is that which stresses the cultural value which the subject possesses". The cultural value of science is derived from its many lessons. We learn of the littleness of our powers and actions, and at the same time we are encouraged to increase them by observing, thinking and planning. The cultural side of science teaching brings us also into close relations with all our efforts to make the pupils see what is good and beautiful. It might well give them happy interests in their leisure time.

Here we are at one with the British Association Committee in that the humanities and science should work together. Whatever is done at the dictates of the humanities is based upon observation of the world, its natural processes and the behaviour of living things. While the humanities study the doings of men, natural science helps to explain their conduct: while the humanities teach us to work for the common good, science shows us how to make goodwill more effective.

Taking the views here expressed of science in education, the Norwood Committee's Report is far from encouraging. In fact, it is frankly disappointing. Its references to science are sometimes vague and frequently outmoded. It is difficult, for example, to understand the remark in the introduction to the Report that: "We have no sympathy, therefore, with a theory of education which pre-supposes that its aim can be dictated by the provisional findings of special Sciences, whether biological, psychological, or sociological, that the function of education is to fit pupils to determine their outlook and conduct according to the changing needs and changing standards of the day".

In Chapter viii of the Report we find support for our views so far as the lower forms of secondary schools are concerned. It is there suggested that science should take the form of a general approach to the main fields. This approach has now become known as general science, and the Committee proposes that the study of natural science here should be related wherever practicable to the everyday experiences of the pupils and should be drawn from the whole field of natural science and treated as a coherent whole, so that the questions of the division into separate science subjects such as physics, chemistry, biology, astronomy and geology does not arise. Furthermore, we are glad to see the Committee deprecating a tendency which is extant in many of our schools, namely, allowing the school environment to dictate too much what kind of science shall be taught, for, as the Committee emphasizes, this causes a syllabus to become over-specialized. For example, in rural schools it is natural that interests in agriculture and rural industries should take pride of place, but there is a tendency to take this too far, for many of the children in such schools have no interest in such industries, and thus they become the victims of a one-sided education for which they are not suited.

When discussing science in the main school, the Norwood Committee makes very few suggestions towards genuine reconstruction. It still discusses scarcely anything but the subjects of physics, chemistry and biology. It is true that it speaks in favour of general science; but this subject is still in the experimental stage, and the Committee makes no constructive suggestions for further experiment along these lines. General science is still, in most cases, a potpourri of physics, chemistry and biology. Pride of place is given in the Report to the problem of the pre-medical students. It is to be hoped that eventually no school will feel disposed to look upon any follow-up university course as dictating its policy.

While, therefore, the main forms of the secondary schools are still allowed to look upon science as being composed of scarcely anything but physics, chemistry and biology, the outlook for science as a true educational tool still remains grave. The Committee's suggestion, however, that science teaching should be remodelled on lines which will attempt less factual knowledge but a surer grasp of principles and methods is more encouraging.

In the Report, the history of science is only hesitantly mentioned: the social implications of science are almost completely ignored. In fact, almost everything suggested in Chapter viii of the Report has been suggested time and time again: for example, the Board of Education Pamphlet No. 89 says: "A knowledge of the facts and principles gained by scientific workers should result in a more rational mode of life; not only is such knowledge of benefit to the individual, but to the community as a whole". This statement goes further along the road towards reconstruction in science teaching than does the Norwood Committee.

Few of the children being taught to-day will become research scientists, but all of them will grow into citizens, who, as part of the State, ought to take an interest in public well-being and the health and happiness of their fellows, and all will carry with them to the end of their days a living body obeying certain laws.

Prof. Julian Huxley expressed somewhat similar views on the Report in the *Times Educational Supplement* of August 28. He points out that science will continue to be the chief agency in man's control of his own destiny, yet there is no recommendation in the Report that science could, let alone should, be taught in a social context. On the other hand, strong emphasis is placed on the social relevance of art. Lack of balance in its attitude towards science is, as pointed out by Prof. Huxley, betrayed by the Committee in its advice to teachers to give definite instruction about the 'limitations' of science and scientific method (sound and wise advice), yet without giving similar advice concerning art, history or religion. We agree with Prof. Huxley that the points raised by the Committee are so stressed as to become a virtual denial of the social relevance and of the social function of education. "They need reformulation by those who think in terms of facilitating social change instead of (perhaps unconsciously) resisting it."

Further support for the sociological and scientific approach is given by Prof. Olive Wheeler (*Times Educational Supplement*, October 2), who deplores complacency with traditional ideas and methods of education. "The use of the scientific method of investigation in the various fields of education, the patient discoveries of biologist, psychologist, and sociologist concerning the nature, development, and varieties of individuals and societies, as well as the experience of practical teachers, will be needed to provide detailed content to this ideal of education in any effective planning."

As Mr. J. B. Priestley pointed out in an address to the International Youth Centre on September 18, return to the old world of 1939 is neither possible nor desirable. In future, there must be a planned society. The old idea that if a man seeks self-interest the good of society will result might have been true in another age, but it is not true to-day. To-day and to-morrow must see co-operative endeavour. But we cannot plan a society which we do not understand, and understanding can only be assured by scientific research and scientific education.

We fully realize that the social sciences and the social implications of science are not easy to teach, especially to such young pupils. But in spite of this the social sciences should be developed in our schools because (*a*) they are very effective in facts and ideas ; (*b*) they can be made far more interesting to the average child, who does not intend becoming a professional scientific worker, in that they show a closer community with man and his environment ; (*c*) they rely less on routine, time-destroying laboratory experiments, but lead to demonstrations and experiments on the self and other activities such as visits to farms, factories, water-works, hospital laboratories, council chambers, etc., and to talks from such officials as politicians, foreign visitors, medical officers of health, nurses, and so forth.

In our schools science should be utilized in the study of such problems as individual and public health, of nutritional standards, housing, population movements, race and nation, family life, of the relations and responsibilities of one person to another, and of the social policy of the State. Thus can the question of personal conduct, moral values and character formation be effectively approached. Though a certain amount of fundamental principles such as is found in the present-day subjects will of necessity be taught, all this cannot be covered in the usual sections of physics, chemistry and biology. (As a correspondent in the *Times Educational Supplemen* of September 25 writes : "The Norwood Report cannot get away from the 'subject' mentality". The sooner our educationists tear themselves away from this subject bogy, the sooner will science come into its own as an educational discipline of the first order.

Prof. A. G. Tansley put the matter ably in his Herbert Spencer Memorial Lecture at the University of Oxford in 1942 : "Scientific culture, then, must take its place on equal terms beside literary and artistic culture. . . . Why, then, we naturally ask, is science regarded with dislike and distrust by too many cultivated people who are supposed to have a libera education, and by the great majority of the population as a rather mysterious, esoteric agency which produces all sorts of mechanical contrivances but in which they have no part or lot ? It is . . . *because scientific education has been kept in watertight compartments and almost exclusive stress has been laid on its material achievements to the neglect of its cultural values.*"

Science stands to gain little and to make scarcely any headway in our educational system until its value as a medium of real culture, apart from its vocational value, is recognized by all, and especially by educationists. For after all is said and done ignorance of the public and its lack of appreciation of intellectual disciplines is invariably due to lack of education, or at any rate knowledge.

THE UNIVERSITY IN MODERN LIFE

ONE of the factors responsible for the greater interest which is now being taken in educational reform is the realization of the extent to which technical efficiency depends on education. The point has been made repeatedly with regard to our export trade and is reiterated in a recent Chatham House paper, "Industrialisation and Trade". In this study, of the changing world pattern and the position of Britain, Mr. A. J. Brown points out that there is ample evidence of room for improvement on pre-war practices through the more effective training, recruitment and use of managers and technicians, both industrial and commercial, in respect of which Britain has lagged sadly behind some other countries, and he stresses the urgency of this matter.

Another factor focusing attention on education especially higher education, as the last man-power debate in Parliament has shown, is the dependence on efficient management of wise use of our reserves of man-power and woman-power. That is the only sure means by which, whether in the Fighting Services, in the Civil Service, or in production, we can ensure that the maximum use is made of the limited resources we possess. The opposition to the extension of the call-up of women, as that debate clearly showed, is not opposition to a higher age limit in principle, but arises from doubts as to whether any effective use will be made of the services of the women ffected—doubts, in fact, whether all the effort volved may not in the aggregate be merely robbing eter to pay Paul.

Fundamentally, as the examples of the misuse or buse of labour cited in the debate indicate, this is n indictment of management, and both in the Civil ervice and in industry there can be no doubt of e shortage of managers and administrators of firstte quality. That is part of the price we must pay r the neglect of scientific management during recent ecades, and it is idle to expect the position to be ectified overnight. The warning must be heeded one the less, and every effort made now to see that e are not again placed in a similar position. Morever, it is as important in regard to post-war reconruction as in relation to the immediate prosecution f the war effort. This point is well brought out by r. H. E. Dale in his Sidney Ball Lecture, "The ersonnel and Problems of the Higher Civil Service", hich has recently been published as Barnett House aper No. 26. However inadequate his suggestions r Civil Service reform may appear—and there are o doubt some who will regard his attitude on comulsory retirement and on a staff college as reactionary -he at least makes it abundantly plain that the uality of the Civil Service is intimately related to e vitality and adequacy of the whole educational stem of Great Britain. Reforms which eliminate diminish the numbing effects of the examination stem and supplement that system with other vital sts equally free from the dangers of favouritism or ass prejudice, which encourage the understanding f men and affairs, will react on the Civil Service no ss than elsewhere. Mr. Dale is on firm ground in aintaining that any staff college or refresher courses ould encourage contacts with men of other prossions and occupations outside the ranks of the ivil Service itself, and that they would be better eld at universities rather than concentrated at a ecial institution.

The contribution of the universities in this matter training for leadership, both those who are entering dustrial or professional life for the first time, and ose specially marked out for high administrative sponsibilities at a later stage in their career, or, ain, in the provision of refresher courses, cannot ell be assessed without some reference to the broad estion of the function of a university in a modern mmunity. That was indeed one subject discussed the conference arranged by the Association of ofessors and Lecturers of Allied Countries in Great itain last April. It has received some attention an interim report of a committee of the British ssociation on Post-War University Education and atured in a recent House of Lords debate on ientific research.

Recent events and the White Paper on Educational econstruction have brought the whole question to e forefront. The British Association Committee commended that entry to universities should as a le be deferred until after a year of approved national international service, whether civil or military. hat suggestion was endorsed by the Nuffield College Statement on Industry and Education", and has in part been taken up by the Norwood Committee on Curriculum and Examinations in Secondary Schools, which recommends that full consideration should be given to the educational and social advantages of the performance of public service for a period of six months falling between school and university or other courses of higher education.

Although, therefore, the Norwood Committee was only indirectly concerned with university education, it is clear that its proposals are designed to encourage the type of reform in higher education which Mr. Dale has in mind. That much follows from the specific pronouncements in the brief section of the Report referring to universities and colleges. The Committee, for example, does not believe that it is to the interest of the nation that entrance to the universities should be of a purely competitive nature, regard being paid solely to achievement in a written examination. That is Mr. Dale's contention and it is implicit in the conclusions of the Nuffield College statement also. Again, the Norwood Committee records a veiled warning against overstocking the country with university graduates of mediocre capacity and attainment, and also its conviction that residence in a college or hostel, at any rate for the major part of the course, is essential to the fullest university life. It regards the encouragement of more life in common, together with an extension of the tutorial system to which residence would contribute, as among the most urgent needs in the development of the newer universities. The university, it holds, will best be enabled to fulfil its function in the life of the nation if it brings together within its walls men and women drawn along many channels from all sections of the community and possessing endowments of intellect and character of a high order. Such reasons alone would enforce reconsideration of the whole position of the universities in the proposals for educational reconstruction, apart altogether from the influence which the universities exert on the school and scholarship examination system, which properly fell within the terms of reference of the Norwood Committee.

The position and function of the university is ably discussed by Mr. Bruce Truscot in his lively volume, "Redbrick University"*, which could scarcely have appeared at a more opportune moment. Possibly, indeed, it is too lively, for while he does not fail to focus attention on the fundamental questions as to the real place of the university in a modern community, he writes with such vivacity on so many secondary questions that discussion of the primary questions is at times interrupted, if not confused, by the secondary controversies his mordant wit provokes.

The criticisms and conclusions which emerge from Mr. Truscot's comprehensive survey fall into two categories: those relating to questions of broad policy or objectives, and those relating to the technique by which policy is to be implemented and objectives realized. However far we may accept Mr. Truscot's own conclusions and suggestions in either field, his first main conclusion is common to both: "The first reform, which must precede all the rest, is the allocation to the modern universities of a Treasury grant many times larger than at present". Even if some of Mr. Truscot's suggestions achieve all that he anticipates in securing that the present resources are expended more effectively, his book makes it abundantly plain that the modern universities need a far larger annual free income to do the work they wish to do, and which they are capable of doing, as well as liberal grants for capital expenditure. The weakest spot in the White Paper on Educational Reconstruction is, in fact, the meagreness of the proposed grant for technical and adult education.

---

* Redbrick University. By Bruce Truscot. Pp. 191. (London: Faber and Faber, Ltd., 1943.) 10*s*. 6*d*. net.

Mr. Butler obviously wishes to develop much closer collaboration between industry and commerce and the education service, and to associate the technical colleges and art schools more fully with the industrial and commercial life of Great Britain. Even in the fourth year of his plan, however, the additional expenditure contemplated on technical and adult education together from public funds is only £100,000 more than that of the unreformed post-war years; and this sum is quite inadequate for any major advance towards a system in which the technical education of potential skilled workers, industrial leaders, and commercial executives is no longer left largely to the initiative of the young employees themselves. Certainly it precludes any attempt to develop the large technical colleges under State control into higher technological institutes of the type encountered in European countries and the United States, engaged primarily with higher technological teaching and with technical research and development.

This point was made in the House of Lords debate on scientific research, notably by Lord Pentland, who urged the desirability of such institutions as the Massachusetts Institute of Technology, and the importance from the point of view of scientific research of adequate endowment of both universities and technical colleges was well put by Lord McGowan. Educational policy, no less than the organization of scientific and industrial research, demands that we should have clear ideas of the place of the universities, the technical colleges, and the special research institutions in our educational system and research structure, and of the functions they are to serve. That is the first essential before we can consider profitably their inter-relations, and apportion wisely the available national resources.

On this question Mr. Truscot's ideas are clear and challenging. To their exposition, indeed, he devotes three if not four of his seven chapters. The core of his argument is indeed in the second chapter, which is a spirited defence of the idea of a university as a corporation or society devoting itself to a search after knowledge for the sake of its intrinsic value. He unhesitatingly maintains that research rather than teaching is the essential function, and challenges Sir Charles Grant Robertson's denial that a research institute cannot be a university in the purest sense of the word. The two aims and the two functions should indeed be there, but the primary aim must be the search for knowledge, the creation and cultivation of the spirit of discovery. The discipline of research is as much more beneficent than the discipline of conscientious teaching and application to knowledge as research itself is a nobler activity than teaching and learning.

On this question of research Mr. Truscot writes wisely and convincingly, and his criticism of much of what passes for research is no less trenchant because in contrast to Flexner, his criticism is constructive rather than destructive. The case for academic research could scarcely be better presented than in the chapter he devotes to this question, and his constructive ideals are set forth persuasively and suggestively. That chapter should do much to restore the dignity of a word often debased in current usage and to demonstrate the place which research should occupy as the inspiration and crown of a libera education. Nor is it without relevance to the conditions which are conducive to research of the highest calibre, whether conducted within the walls of a university, a Government department, or the laboratories of an industrial firm.

Although the first place is given to research, the discussion of teaching in this volume is no les stimulating and penetrating. Mr. Truscot effectively disposes of some of the cruder views advanced at some of the National Union of Students conferences If 'freshmen' came to the universities with a burning desire for general knowledge, he remarks, they would find ample means of feeding it, even as the universities are at present. Again, he points out that it i only when one begins to know a subject deeply tha the critical faculty has any real scope. Only by seeing that students' knowledge is sound and deep, and a the same time seeking to inspire them with the spirit of adventure and research, can we ever develop a critical faculty in them at all. That is done, primarily through the honours course, and to a lesser exten through a general course of not more than three mai subjects, of which one at least has close relations with one or both of the others.

Mr. Truscot makes a sound defence of the lectur system and of the honours system within limits, an suggests that premature specialization should b looked for in some of the subjects in the Highe Certificate examinations rather than at the university. His fundamental argument is that the whole art o educating the undergraduate, in the deeper sense must be based upon instilling into him the true ide of the nature of a university. This is one of the reasons for his insistence upon the research function for it cannot but facilitate the break with traditio and the text-book. The student who has throw off such shackles, developed a limited trust in his own judgment and a desire for the time to come when he can trust it more, has, as Mr. Trusco remarks, learned the inner meaning of university education.

The emphasis on the necessity of imparting the ide that the undergraduate's teachers at the university—his fellow-members—are not so much teachers as collaborators, learners like himself but in a con derably higher class, and his remarks on the place the university library in stimulating thought, are no ss sound and suggestive. But although he represses e excess of vocational aspirations, Mr. Truscot cognizes that vocational training has its place. In e ideal of service all three functions—research, aching and vocational training—have their natural eeting place, and this keynote of service inspires e concluding chapter of the book, on the external ntacts of the university. Here, too, are vision d insight on the contribution which the modern iversity might make to the service of the community in the city and district which are its home, d from which the majority of its students may be awn. On the measure in which are fulfilled those ssibilities of adult education, such as the interetation of the issues involved in current political d international affairs, and appreciation of the nctions of the Press, the future of democratic titutions may well depend.

Mr. Truscot's book is full of practical common nse. He deals with practice as well as theory, and his vision of the university and its contacts he can rn aside, for example, to enunciate sound rules for ccessful lecturing. But no less than Newman and exner, he has a vision of the greatness of the iversity ideal, and senses the dangers from within its high traditions of independent and creative ought; the note of service which he strikes insistly is no less persuasive because his ideals are linked h plain counsel on the technique by which they to be achieved. Finance, indeed, is a first conion, and above all more generous endowment from State if the universities are to play a worthy part the post-war world. But they also need insight d vision for wise planning, common sense, deternation and energy. Mr. Truscot's little book erves to be widely known and read, for it should ke a modest but effective contribution in stimung the reforms from within, the clearing away of bish, and pruning of dead wood, which are as ential as adequate endowments if the universities to follow in the coming age their high traditions service and of leadership, and to seize the wider portunities now before them.

"STUDENT" AND THE NEW BIOLOGICAL STATISTICS

udent's" Collected Papers
ted by E. S. Pearson and John Wishart. Pp.
+ 224. (London: Biometrika Office, University
lege, 1943.) 15*s*. net.

would be idle to suppose that biologists are making ull use of the powerful tool given to them by modern istics, or even that they are likely to make full of it before statistical teaching has improved. ertheless it cannot be denied that notable adces towards this desirable end have been, and being, made. The biologist is at least coming to ize something of the value of statistics, and to rd the statistician as a welcome ally, who will st in making the most of limited experimental resources, rather than as an unhelpful critic, likely to reject the results of laborious experiments as constituting too small a sample to permit the drawing of statistically reliable conclusions.

This changing attitude reflects, indeed is conditioned by, a corresponding change in statistics itself. Until thirty-five years ago the statistician had no means of treating a small body of data on its merits. It was, of course, to him a sample from a larger population, and if the quantities defining that population, parameters as they are called, were known, the properties of the sample could be deduced. But there was no way of deducing these properties from the sample itself, because a sample yields only estimates of the basic parameters. Estimates are subject to sampling error, and the smaller the sample the larger this error is likely to be. Thus analysis was of necessity confined to samples sufficiently large for estimation to be regarded as yielding the 'exact' values of the parameters within very close limits. Beyond this the statistician dared not go, for his methods ceased to be applicable. Most experimental work in biology was thereby excluded.

Now, however, the distributions of quantities based solely on the estimates, and independent of the exact values of the parameters estimated, have been determined. Assumptions concerning the parameters, as distinct from their estimates, need no longer be made, and rigorous analysis of small bodies of data has become possible. The rich development of this field must always remain associated in a special way with the work of Fisher, but "Student" will be remembered, too, as the man who, without being primarily a mathematician, first saw in 1908 the possibility of this new approach, and who calculated the first of the distributions which make possible the confident analysis of small samples.

W. S. Gosset, to give "Student" his real name, published twenty papers and six shorter communications between 1907, when he was thirty-one, and his death in 1937. A twenty-first paper appeared posthumously in 1938. Though fourteen of these papers were published in *Biometrika*, the remainder were scattered throughout eight other journals. We are thus indebted to Prof. E. S. Pearson and Dr. J. Wishart for now making possible a balanced appreciation of the work of this remarkable man by collecting these papers into one volume.

"Student's" papers fall into three groups. Up to 1919 he was mainly concerned with what may be described as distributional problems, and this phase includes the paper (1908), for which he will be mainly remembered, containing his derivation of the forerunner of the modern t distribution. (His tables of t were finally published in 1925.) This had been preceded by his consideration of the distribution of hæmacytometer counts, which were shown to give a Poisson series, and was followed by a somewhat less successful consideration of the distribution of the correlation coefficient. The remaining papers of this period are of less general interest, though in an appendix to Mercer and Hall's article on field trials (1911) "Student" foreshadows his later work on agronomical trial design. This topic forms, in fact, the subject-matter of the majority of the papers of the second group, from 1923 until his death. Interposed between the groups is a discussion (1921) of the efficiency of Spearman's correlation methods, and there is later (1927) an account of the errors of routine analysis. The third and smallest group consists of two papers on the genetical theory of selection, in which he points out the immense evolutionary importance of the store of heritable variability which a group of organisms will generally possess. In these papers, too, the estimation of the number of genes affecting oil content in Winter's maize is attempted.

The reader of this collection cannot fail to be impressed by the way in which most of the papers, including, we venture to say, all of first importance, are concerned with problems encountered by the author while engaged as a scientific worker in the employment of Messrs. Guinness. His consideration of estimating yeast density by hæmacytometer counts, his long interest in field trials of barley varieties, his discussion of the errors of routine analysis, all reflect different aspects of this work; and, above all, his derivation of the ratio he termed *z* (not to be confused with Fisher's *z*), later to be transformed into *t*, reflects the necessity for drawing, from small samples, conclusions of a reliability sufficient to serve as the basis for executive action. Herein we can find the clue to "Student's" success; he was an experimental scientist who knew what he wanted statistics for, and when existing methods failed him, undertook for himself the development of new ones which would work. His mathematics was not always of the most elegant, indeed it was on occasion neither fully rigorous nor wholly successful; but he always tackled the problems which faced him in a downright fashion, using experiment and arithmetic to check his algebra, by methods which must appeal to all those of us who, like him, are not professed mathematicians yet find statistical analysis essential in our experimental work.

"Student" ushered in the new era of collaboration between statisticians and experimenters. But his work was not only hampered by the statistical conventions of his early days; it seems also not to have been fully appreciated by some of his statistical associates, for so late as 1931 we find him defending his small sample test against criticism by Karl Pearson. Nor did "Student" realize the full consequences of his great discovery. The moulding of statistics into the powerful weapon of to-day awaited Fisher, and the effects of Fisher's influence is to be seen in many of "Student's" papers after 1915. In the 1930's, something of a controversy developed between the two, on the necessity for randomization in field trials, and here "Student" took the curious stand that, while we must "superpose randomness on the biassed fertility of the soil", this could as usefully be done by certain systematic arrangements as by actual randomization of the plots. Indeed he claimed in his last paper that not only could sampling error be minimized in this way, but that even if it led to a slightly biased estimate of error, the bias was in a helpful direction.

It would, however, be surprising if "Student's" papers did not in places seem open to criticism by the reader of 1943. Nor can such criticism detract from the value of a volume of this kind. These papers are primarily "Student's" record of his results and findings; but they also reveal to us the needs which prompted his work and the way in which he set about it. Few experimenters can fail to derive a new confidence for the attack on their own problems from seeing how his clear recognition of the statistical needs of experiment, and his practical approach to their satisfaction, enabled "Student" to mark the way to the new statistics, the benefits of which we can now enjoy.

K. MATHER.

OPTICAL METHODS IN CHEMISTR

Optical Methods of Chemical Analysis

By Dr. Thomas R. P. Gibb, Jr. (Internation Chemical Series.) Pp. xiv+391. (New York McGraw-Hill Book Co., Inc.; London: McGra Hill Publishing Co., Ltd., 1942.) 35*s*.

LIKE so many other activities, analytical chen istry is becoming mechanized. A training the standard procedures of gravimetric and vol metric analysis is, of course, still essential for tl chemist, but it needs to be supplemented by e perience in the use of a large variety of instrument many of which are optical. Dr. T. R. P. Gibb is a instructor in analytical chemistry at the Massach setts Institute of Technology; he has managed (quote his preface) "to present a compact, abridge survey of optical methods of analysis in a sty suited both to the practical analyst and to tl advanced student of analytical chemistry". H teaching experience has obviously been gained i splendidly equipped laboratories, and the problen given at the end of each chapter are a clear indicati that the task of teaching the newer analytical metho is being tackled on a scale and with a gusto hither impossible in Great Britain.

It is impossible to avoid comparing this book wi some of its predecessors. Löwe's "Optische Messung des Chemikers und des Mediziners" (Steinkop Dresden and Leipzig, 1933) is a very useful technic progress monograph for research workers, while Fri Weigert's classical "Optische Methoden der Chemi (Leipzig, 1927) remains the best comprehensive wo for the serious student of the subject, although it to some extent out of date as regards the design instruments. It seems unlikely from the text th Dr. Gibb has seen either of these books, but in spi of that handicap he has written a very usef laboratory handbook.

The chapter on spectrochemical analysis provid a skilfully chosen minimum of information f effective practical work. His treatment of spectr photometry displays more interest in instrumen than applications and is, perhaps, a little unbalanc on that account. Any chemist inexperienced in tl use of microscopes, colorimeters, nephelometers fluorophotometers, will find the construction of su instruments and details of their manipulation giv very lucidly. Dr. Gibb has an excellent account elementary crystallography, and his description the identification of crystals with the polarizi microscope will be of special interest to unive sity teachers who are concerned with the revisi of practical chemistry curricula. The refract meter and the polariscope are quite adequate treated.

The book as a whole is clearly written and effective illustrated. The selection of references for furth reading has been done well, but theoretical conside tions and the general problems of interpretation ha been dealt with too cursorily. The chemist q skilled technician will find the volume admirab but teachers in Great Britain may doubt wheth the scales have not been tipped too far on the si of sheer technique. In terms of the programme ou lined in this book, universities and colleges outsi the United States are seriously under-equipped the teaching of modern analytical chemistry, a the scales are weighted in the opposite directio

R. A. MORTON.

THE SIGNIFICANCE AND DEVELOPMENT OF HAMILTON'S QUATERNIONS

By Prof. H. T. H. PIAGGIO

University College, Nottingham

A HUNDRED years ago, on November 13, 1843, Sir William Rowan Hamilton read to the Royal Irish Academy his first paper on quaternions. The centenary is being celebrated by the Academy, and the Government of Eire is issuing a special postage stamp commemorating Hamilton's work. Hamilton's treatises, in the opinion of Prof. P. G. Tait, an "only be compared with the 'Principia' of Newton and the 'Mécanique Céleste' of La Place as a triumph of analytical and geometrical power". On the other hand, Lord Kelvin declared that quaternions, "though beautifully ingenious, have been an unmixed vil to those who have touched them in any way, including Clerk Maxwell". It is difficult in the present relativist age to be as certain of anything as the Victorians were of everything, and we shall examine the conflicting points of view, indicating both majority and minority opinions. But before discussing these controversial matters, it is advisable to recall the facts concerning Hamilton and his discovery.

Hamilton was born in Dublin on August 3, 1805. He showed signs of great ability at a very early age. He could read well at the age of three. At five he translated Latin, Greek and Hebrew, adding Italian and French at eight. At ten he began Arabic and Sanskrit. At twelve he had studied Syriac, and had also engaged in contests with Zerah Colburn, the American 'calculating boy'. Hamilton was defeated, but he was able to analyse Colburn's methods, which Colburn himself did not fully understand. Possibly this was partially responsible for turning Hamilton's attention to mathematics, though for some time he devoted at least as much of his time to languages, chiefly Latin and Greek, but also Sanskrit, Persian and other Oriental tongues. He entered Trinity College, Dublin, in 1823, and was first in all subjects at all examinations. His career as a student ended in an unprecedented way; he was, while still an undergraduate, elected in 1827 as professor of astronomy. The observatory was badly equipped, and Hamilton lacked the immunity to cold necessary o a successful practical astronomer. Perhaps this was really fortunate, for otherwise he might have wasted, in routine observing, time and energy more profitably devoted to research in mathematical physics. In 1828 he published the first instalment of his researches on optics, which led on to his fundamental work in dynamics. To explain this would take a whole article in itself. All that is relevant here is that, although the real magnitude of the achievement could not be fully appreciated until the creation of modern quantum dynamics in 1925–26, it was realized sufficiently to give Hamilton a great reputation. One particular piece of work, the prediction of conical refraction in crystals, was easily intelligible to both mathematicians and physicists, and this spread Hamilton's fame far and wide. He was knighted in 1835.

The discovery of quaternions had little or nothing in common with Hamilton's researches on mathematical physics, but arose out of difficulties in elementary algebra. The occurrence of i, which denotes the square root of minus one, in roots of quadratic equations, was for long regarded as an algebraic fiction, from which, surprisingly enough, true results could be obtained. Then several contemporary writers, Wessel (1797), Argand (1806) and Gauss (1831), found an explanation. If we consider i to be an operator which turns a line through a right angle, the 'complex number' $x + iy$ represents a point P obtained by going a distance x along a line Ox, say to N, and then a further distance y along a direction NP perpendicular to ON. Alternatively, we may consider $x + iy$ to represent, not the point P, but the displacement of O to P, or again the line OP. It then appears that the addition of two complex numbers exactly corresponds to the compounding of two forces by the parallelogram of forces. Instead of forces we may consider velocities or accelerations. All these quantities, which have both magnitude and direction, may be called *vectors*, and so the addition of complex numbers corresponds to the addition of vectors, and similarly for subtraction. When we come to multiplication of one complex number by another, we find that the process corresponds to the combined turning and stretching of a vector, producing another vector in the same plane, and similarly for division.

Hamilton pondered for many years over this geometrical theory of complex numbers, and gave an alternative treatment, purely algebraical, in which $x + iy$ was considered as a couple of real numbers x and y, obeying certain laws of operations. The full importance of this did not appear until much later. The immediate question that arose was why algebra should correspond to operations confined to one plane. It was easy to think of the addition of vectors in space, but what was the corresponding complex number which Hamilton considered as a *triple* of three real numbers x, y and z? It seemed as if we needed something like $x + iy + jz$, where j had properties somewhat similar to those of i. More symmetrically, Hamilton considered $ix + jy + kz$. But the central difficulty was how to multiply such numbers. This problem had already defeated mathematicians of great ability, though it is now known that Gauss, in a brief abstract which he wrote probably about 1819, but never published, seems to have anticipated some of Hamilton's work. Hamilton struggled with the difficulty for fifteen years, sustained in the later stages by the sympathy of his family. "Well, Papa, can you *multiply* triplets?" was his breakfast greeting from his two little sons, aged eight and nine, and he had to shake his head sadly and reply that he could only add and subtract them. But on October 16, 1843, when he was walking with his wife along the Royal Canal, "an electric circuit seemed to close and a spark flashed forth", and he suddenly saw that the solution of his difficulties could be found if he postulated the rules $i^2 = j^2 = k^2 = ijk = -1$.

In his enthusiasm Hamilton cut these symbols on a stone of Brougham Bridge. The incident has been the subject of a drawing by the Irish artist, Sean Keating. The real novelty of these postulates lies in the implication that $ij = -ji$, a *non-commutative* law of multiplication. This would be obviously untrue if i and j were ordinary numbers. But consider a sphere of centre O, with three mutually perpendicular radii Ox, Oy, Oz, and a rod, of length equal to the radius, freely pivoted at O. Guided by the meaning given to i in two dimensions, let us now interpret i as a rotation through a right angle of the rod about the line Ox, bringing its free end from y to z. Similarly

j brings it from z to x, and k from x to y. We take $-i$ to reverse the operator i, and so to bring the free end from z to y. Now we can bring it from x to y by bringing it from z to y, after having previously brought it from x to z. This gives $k = (-i)(-j) = ij$. Similarly we can bring it from y to x by bringing it from z to x after previously bringing it from y to z, so $-k = ji$. On this interpretation the non-commutative law $ij = -ji$ becomes obvious.

Having got over the difficulty of multiplication, Hamilton next considered division. He found that the quotient of two vectors, like their product, was not itself a vector, but the sum of a vector and a *scalar* (that is, a quantity having magnitude but not direction), say, $w + ix + jy + kz$. As this was the sum of four parts, he called it a *quaternion*. Although his first approach had been algebraical, he now founded his system on the quaternion defined as the geometrical operation (a combined turning and stretching) that converted one vector into another. All mathematical operations such as addition, subtraction, multiplication and division of quaternions resulted in other quaternions, so the way was now clear to build up a complete system, and to explore its numerous applications to geometry, physics and astronomy. To this task Hamilton devoted the remaining twenty-two years of his life, asserting that "this discovery appears to me to be as important for the middle of the nineteenth century as the discovery of fluxions was for the close of the seventeenth".

Many shared this view, and Hamilton was lionized by Dublin society. In England, quaternions were welcomed and used so early as 1845 by Prof. A. Cayley, the greatest of British geometers. Great enthusiasm was aroused in the United States. In Edinburgh, Tait became the fervent apostle of the new mathematical gospel, and investigated the physical applications of the symbolic operator ∇, which, applied to a scalar, gives the direction in which that scalar increases most and the magnitude of its rate of increase per unit distance. Tait also produced "An Elementary Treatise on Quaternions" (first edit., 1867, second edit., 1873, third edit., 1890), which was very much easier to understand than either Hamilton's "Lectures on Quaternions" (1853) or his posthumous "Elements of Quaternions" (1866). Hamilton's books were both very long (about 800 pages each) and suffered from over-elaboration. At first it seemed as though Tait's force of enthusiasm would be irresistible, but he met an immovable wall in Sir William Thomson (Lord Kelvin), the co-author of the well-known "Treatise on Natural Philosophy". Kelvin wrote in 1901, of Tait: "We have had a thirty-eight year war over quaternions. . . . Times without number I offered to let quaternions into Thomson and Tait if he could only show that in any case our work would be helped by their use. You will see that from beginning to end they were never introduced". The attitude of Clerk Maxwell was less rigid. He considered that "the introduction of the ideas, as distinguished from the operations and methods of Quaternions, will be of great use, . . . especially in electrodynamics. . . ." Accordingly he suggested to Tait the use of the words *curl* and *convergence* (now replaced by its negative, *divergence*). However, in Maxwell's own treatise on "Electricity and Magnetism" quaternions appeared in only a few places. The general attitude of mathematicians and physicists was summed up in Maxwell's phrase: "The unbelievers are rampant".

But even more painful than the stubbornness of unbelievers was the lapse into heresy of some wh had at first accepted the true faith. Cayley's earl enthusiasm had cooled into the comparison quaternions with a pocket map, which containe everything but had to be unfolded into another for before it could be understood. The physicists remarked that quaternions themselves were not use so much as their scalar and vector parts. Why no said the American mathematical physicist, J. W Gibbs, discard the useless quaternion, and set up vector calculus, starting with simple geometric definitions of the vector and scalar products of tw vectors, and altering Hamilton's sign in the scal product so as to get rid of his ridiculous result tha the square of a vector was negative ? The quaternio ists pointed out that quaternions could not be avoid if we were to consider the quotient of two vector The vectorists replied that they had no need to co sider quotients, which were not required in physic All Tait's arguments for the utility of quaternions physics were seized and used against him, for the became even stronger when applied to vector analysi The controversy between the two sides raged wit almost theological bitterness[1]. Even more confusio was created when the vector analysts themselv split up into sects, differing only on minor points notation. A saner attitude was shown by C. J. Jol one of Hamilton's successors as professor of astronom at Dublin, and editor of the annotated second editio of Hamilton's "Elements of Quaternions" (1899 an 1901). Fully conscious of the logical completene of that great work, he nevertheless realized that mathematician whose time is limited may be frigh ened by the magnitude of Hamilton's bulky tome Joly, therefore, in his "Manual of Quaternions (1905), reluctantly abandoned Hamilton's method and started with Gibbs's definitions, except that th sign of the scalar product was different. Joly the defined a quaternion as the sum of a scalar and vector, and proved its fundamental laws. This metho appears to combine many of the advantages of bot schools.

Many mathematicians consider that the true valu of quaternions lies in their extension of the idea number. Hamilton's theory of couples was the fir step in the creation of the abstract algebras whic attract so much attention to-day. The non-commuta tive law of multiplication was the first hint, quick developed by Boole, that there is not one algebr but many, with a wide choice of fundamental post lates. From this point of view Tait's insistence the close connexion between quaternions and physi was, in the end, very unfortunate. For physicist quaternions have been displaced by vector analysi and later, with the advent of relativity, by the tens calculus. For the few surviving quaternionists it adding insult to injury that their supplanters ha stolen Hamilton's term *tensor* and used it in an e tirely different sense ! The tensor calculus al appeals to mathematicians, as it is applicable to a number of dimensions, whereas quaternions a essentially three-dimensional. Another n-dimensio extension of the idea of number, Grassman *Ausdehnungslehre* (calculus of extension) appeared early as 1844. Its merits have been obscured by t defects of its author's presentation, and, moreov it is so very general that there is great difficulty applying it to particular problems.

To sum up, in the opinion of the majority, t spirit of Hamilton's great discovery will survive, bo in pure mathematics and in physics, although t form in which he presented it has become merely of historical interest. But there is also a minority opinion. Prof. E. T. Whittaker[2] points out that Pauli's spin matrices of 1927 are simply Hamilton's *i*, *j*, *k*, and says[3], "I am inclined to conjecture that if the present range of problems were not extended, physicists would continue to prefer vector-analysis; but that the development of relativity and quantum mechanics will sooner or later require quaternion methods for the more difficult problems (as in Professor Conway's paper, referred to in my original article); and that when the physicists have thus been forced to learn quaternions, they will use them for all purposes, and vector-analysis will be forgotten".

DEVELOPMENTS IN MICRO-CHEMICAL ANALYSIS

By E. J. VAUGHAN

A SYMPOSIUM on micro-chemical analysis arranged by the Micro-Chemical Club, the South Yorkshire Section of the Royal Institute of Chemistry and the Sheffield Metallurgical Association was held at Sheffield on October 9, and was preceded by a demonstration of micro-chemical methods and an exhibition of micro-chemical apparatus. The exhibition was very complete in character and included the latest design of micro-chemical balance, capable of weighing one milligram of substance accurately to 1/500 mgm., some physical instruments now used as the tools of the micro-chemist—notably the polarograph and photo-electric absorptiometer—and a variety of graduated flasks, pipettes, burettes and mixing vessels. Of the micro-glassware exhibits one of the most interesting was the Wigglesworth-type burette which was used in the determination of the sodium chloride content of the body fluid of a single gnat. This burette is usually home-made by the micro-chemist, being obtained by drawing out a piece of glass tube to an extremely fine bore, waxing the interior and exterior surfaces and mounting in a suitable glass tube. The waxing overcomes surface tension effects, a drop size something less than that of the head of the average pin is obtained, and each drop breaks cleanly away from the burette end.

The symposium included a number of papers covering a wide range of subjects, and produced some accounts of noteworthy advances made in the application of micro-chemical methods to the analysis of inorganic materials. The study of micro-organic and micro-biological methods has had considerable prominence in the scientific world, and from the evidence submitted it would now appear that the inorganic micro-chemist is advancing as rapidly as his colleagues in the other spheres.

Exigencies of the War have made many demands of the chemist, and not the least of these is the necessity of establishing the composition of metallic compounds when only limited samples are available. A detailed study of this problem has resulted in the formation of micro-chemical methods for the determination of alloying elements in steels and aluminium alloys. It is possible to determine manganese, titanium, copper, vanadium, molybdenum, phosphorus, nickel, chromium and silicon in steels on amounts of sample ranging from 10 mgm. in the case of the first three elements mentioned down to 2 mgm. in the case of the last two, and iron, manganese, nickel and copper in aluminium alloys, the weights of sample required being 10 mgm., 10 mgm., 2 mgm. and 1 mgm. respectively.

The methods are unusual in that they employ a chemical opening out and a physical finish. In all cases, the chemical procedure followed is to take the alloy into a suitable acid solution and then, by application of chemical reagents, form, with the element which it is desired to determine, a complex which gives rise to a coloured solution. The Spekker photo-electric absorptiometer is then employed to determine the light absorption of the solution, the chemical technique having been so arranged that the measured absorption is directly proportional to the concentration of the element being determined. The measured absorption may be obtained as the result of a single reading or the difference between two readings. An example of the former occurs in the silicon method, in which a silico-molybdate complex is formed and reduced by the addition of stannous chloride to molybdenum blue, the final condition of the solution being such that the other elements present do not give rise to a measurable absorption. The determination of manganese provides an example of the latter, for the oxidation of manganese to permanganate by potassium periodate also gives rise to the partial oxidation to dichromate of chromium. The total absorption is first measured, a drop of sodium nitrite to decolorize the permanganate then added, and the absorption due to chromium as dichromate measured.

The most recent advance in this field of work has established a composite method for the determination of manganese, molybdenum, chromium and nickel on a single 4 mgm. sample. This result has been achieved by the use of monochromatic light obtained through the use of a mercury lamp as light source, with suitable filters in the absorptiometer and the provision of specially manufactured micro-cells which may contain as small an amount of solution as 0·5 ml. but yet permit the passage of a narrow beam of light through a long column.

The actual weights of the elements under consideration present in the solution measured are of interest. Assuming each element to be present to the amount of 0·1 per cent of the sample, the weights in the absorption cell are:

Manganese	4×10^{-6} gm.
Molybdenum ..	$1{\cdot}6 \times 10^{-6}$ gm.
Nickel	4×10^{-7} gm.
Chromium	$3{\cdot}2 \times 10^{-7}$ gm.

Accuracy of the determination of such small amounts is claimed, and in each case a ten-division drum movement reading of the absorptiometer is recorded.

An example of a mainly chemical method of attack was provided by an account of a micro-method of gas analysis. The gas bubbles occurring in glass have been studied, means for their extraction developed and a technique for their analysis formulated. The whole process has been so well developed that bubbles of gas of the order of 4×10^{-3} c.ml. can be analysed for sulphuretted hydrogen, carbon dioxide, carbon monoxide, sulphur dioxide, oxygen and hydrogen. In order to extract a bubble of gas, the glass containing the bubble is ground down until it is 1/1000 in. thick, and the glass is then broken under glycerine. The bubble of gas floats to the surface of the glycerine, where it is retained by a microscope slide and its diameter measured by means of a microscope. The bubble is then removed by using a bent capillary pipette with an inner diameter not much smaller than that of the bubble, and transferred to a solution of cadmium acetate. Five minutes contact with this solution removes the sulphuretted hydrogen and the bubble is then transferred by means of the special pipette first to a glycerine-washing solution and then to the original glycerine solution for diameter measurement. The process can be repeated using 10 per cent caustic soda in glycerine for the removal of carbon dioxide, sodium hydrosulphite for the removal of oxygen, ammoniacal cuprous chloride for the removal of carbon monoxide and colloidal palladium solution containing sodium picrate for the removal of hydrogen.

A spot technique has also been devised whereby a very rapid qualitative test for the presence of a single gas can be made. For this purpose, specially constructed instruments for piercing glass are employed, to the contact ends of which the chemical reagents are applied, a microscope being used where necessary to observe any reaction. As an example of this spot technique for the detection of sulphur dioxide, a gramophone needle as the piercer holds at its point an acid solution of fuchsine decolorized with formaldehyde, and after piercing, the formation of a reddish-purple colour indicates the presence of sulphur dioxide in the gas. Although great accuracy is not claimed for this method owing to the fact that the gas bubbles are not always spherical and some of the constituent gases show partial solubility in glycerine, very valuable results have been obtained. It is proposed to compensate for solubility errors by carrying out the same process on samples of known composition.

Of the latest advances in micro-chemical analysis as applied to organic chemistry, the use of mercuric oxycyanide was cited. This micro-chemical reagent has been employed with advantage in the determination of sulphur, by making use of its reaction with barium chloride to form barium hydroxide. The normal sulphur method is followed so far as the precipitation of barium sulphate, a known amount of an accurately standardized solution of barium chloride being added, however, and then hydrochloric acid is removed by evaporation, and the barium hydroxide formed from the excess barium chloride by the addition of mercuric oxycyanide is determined by titration with standard sulphuric acid. The method has distinct advantages in that it permits a smaller sample weight than the gravimetric method, employs the accurate alkali-acid titration finish and overcomes errors due to incomplete precipitation of barium sulphate or co-precipitation of barium chloride. The application of this reagent to bring about an acid-alkali titration finish has been extended to the determination of ionic iodine and the methoxy radicle.

The polarograph has been employed for a number of years for micro-chemical analysis, but a recent innovation is the use of this instrument for amperometric titration. An outstanding example of an amperometric titration is the determination of copper and zinc using quinaldinic acid as the titrating medium. Using the polarograph to give a constant applied potential of $-0{\cdot}9$ volt to the solution of copper and zinc, the changes in current flowing are recorded against successive increments of quinaldinic acid. From the resulting graph, concentrations of copper and zinc are determined.

During the meeting, attention was directed to th lack of facilities in Great Britain for teaching microchemistry. The view was expressed that it can b taught to undergraduates successfully and should b included in the normal chemical syllabus. Detail of a six weeks course, which had been successfull introduced in a university degree course, were given.

In discussion, regret was expressed that facilitie are lacking for the pooling of micro-chemical knowledge—the symposium being specially arranged an being the first of its kind for four years. The meetin concluded by passing a resolution expressing it desire that everything possible should be done t further activities of micro-chemists, and appointe an *ad hoc* committee to consider the best means b which this aim could be achieved.

PROBABLE FUNCTION OF HISTONE AS A REGULATOR OF MITOSIS

By DR. E. STEDMAN, F.R.S., AND MRS. ELLEN STEDMAN

Department of Medical Chemistry, University of Edinburgh

UNTIL the recent discovery of chromosomin[1], th histones (and protamines) were regarded as th typical proteins of cell nuclei, a view which w fairly well founded as regards fish spermatozoa[2], bu which lacked any certain experimental basis wit respect to other and more typical forms of nucle Kossel[3] and Ackermann[4] had, it is true, demonstrate the presence of a histone in the nuclei of avian er throcytes by extracting it directly from the isolate nuclei, but no detailed study was made of its chemic composition and properties. Apart from this i stance, no histone has, so far as we are aware, bee extracted directly from any nuclei other than tho of spermatozoa. Nevertheless, histones have bee isolated from various tissues, in particular from t thymus gland; more recently, Mirsky and Polliste have prepared nucleoproteins, in which the protei component is believed to be either a histone or prot mine, from a variety of animal tissues. There is th presumptive evidence that, while the traditional vie that the protein components of nuclei are chiefly entirely histones is, as we have shown[1], incorrec histones do nevertheless occur widely among t constituents of nuclei. Nothing, however, is know concerning the function of histone in the nucleu Of the two other main constituents, chromosomi the principal component of the chromosomes, mus according to our experiments, represent the chemic basis of inheritance, while there seems little dou that nucleic acid is concerned mainly with spind formation during mitosis and, in combination wit chromosomin, with protein synthesis during t resting stage, the nucleoprotein then formed by the union being analogous to the self-propagating nucle proteins of which the viruses are now believed to b composed.

This picture of the cell nucleus at first sight leav no place for histone. Partly with the object gaining information regarding its function we ha therefore determined the content of histone, as we as of the other constituents, in the nuclei from number of cells of different types by direct extractio from the isolated nuclei. A few of the results we abulated in our previous article[1], but no comment as made upon the evident differences in histone ontent until confirmatory work had been done on e subject. It has now been possible for us to xamine nuclei from further types of tissue, and we re presenting our new analytical results, together ith those previously obtained, in the accompanying ble.

Origin of nuclei	Percentage content of dried, lipoid-free nuclei		
	Histone	Nucleic acid	Chromosomin
Ox spleen	16	34	50
Fowl's erythrocytes	24	43	33
Calves' thymus glands	21	44	35
Cod sperm	12	28	60
Walker rat carcinoma	1·6	26	72·4
Mouse carcinoma 2146	3	32	65
Chick embryos	3	35	62

The main result of our investigation can at once be en from the above table. It is that in the two ypes of carcinoma tissue examined, and in the mbryonic tissue, the content of histone in the nuclei markedly smaller than in nuclei from normal ssue. We believe this to be the most significant sult of our experiments. Nevertheless, it should be oted that the nuclei from the carcinoma and embry- nic tissue contain a greater amount of chromosomin d, on the whole, a somewhat smaller amount of cleic acid than the nuclei from normal tissues.

In order to make the meaning of these results earer it is, perhaps, not superfluous to point out at, of the normal nuclei examined, those from the wl's erythrocytes can be regarded as homogeneous d entirely in the vegetative state. Those from the ymus gland, while not completely homogeneous, nsist to a preponderating degree of thymocytes hich, again, must be considered to be in the per- anently resting condition. On the other hand, the clei from the carcinoma tissue of both types, and om the embryonic tissue, are derived from cells dergoing frequent mitoses. We conclude from is that a high content of histone in the nucleus of a ll produces an inhibition of both the processes hich lead to mitosis and those which lead to the nthesis of the chromosomin necessary for the plication of the chromosomes.

The work described above is not sufficiently vanced for us to discuss all its implications at e present time, particularly its bearing on the ncer problem. There are, however, some tentative ggestions which can, we believe, be usefully made garding the mechanism by which the histone gulates the growth and division of a cell. As we ve pointed out, the histone is a protein with pro- unced basic properties and is, in fact, the only sic substance present in appreciable amount in the cleus. It appears to us to be an indisputable emical necessity for this base, when present in the cleus, to be in salt-like combination with the nucleic id, and it is therefore presumably this combination hich prevents both the synthesis of chromosomin d the division of the cell. So much seems to llow with certainty from our results. How this ect is produced can to some extent be visualized if e accepts the suggestion, which we have made ewhere[1], that the spindle which is formed in the ll during mitosis is composed of nucleic acid. By combination with the latter, the histone would, en present in sufficient amount in the nucleus, so alter the properties of the nucleic acid that the formation of a spindle would be impossible, and hence the processes which lead to cell division would be inhibited. On the other hand, in the absence of large amounts of histone part of the nucleic acid would combine with the basic groups of the chromosomin, causing the latter to be dispersed in the nucleus. In this condition, which would correspond with the resting state of the cell, the synthesis of chromosomin would occur, following which the chromosomes would begin to separate and the spindle to appear. Such a picture of the control of mitosis, although incomplete and possibly inaccurate in detail, serves a useful purpose in emphasizing the part played by the histone in cell division.

We desire to thank Mr. F. Pettigrew for carrying out the necessary implantations of the tumours, Dr. Greenwood and Miss Peace for supplies of fowl's blood and chick embryos, the Moray Research Fund for defraying the cost of the mice, and the Medical Research Council for a grant to one of us.

OBITUARIES

Dr. F. J. W. Whipple

KEW OBSERVATORY has had a long line of superintendents, including Balfour Stewart and Charles Chree, and F. J. W. Whipple was a worthy member of it. He retired in March 1939 with the prospect of much useful scientific work ahead; but to the regret of his friends and old colleagues he died from heart failure on September 25 this year.

Francis John Welch Whipple was born on March 17, 1876. He was educated at Merchant Taylors' School and Trinity College, Cambridge. His university career was brilliant: he graduated as second wrangler and his Smith Prize paper was highly commended. For a few years he returned to Merchant Taylors' as mathematical master; then in 1912 he joined the Meteorological Office. For thirteen years he worked at the headquarters office in London, first as superintendent of the Instruments Division and then of the Climatology Division. In 1925, Dr. Charles Chree retired from the superintendentship of Kew Observatory and Whipple was appointed to succeed him, being promoted at the same time to the rank of assistant director of the Meteorological Office. This change was welcomed by Whipple for personal reasons, for his father, G. M. Whipple, had been superintendent of Kew Observatory during 1876-1893, and his maternal grandfather, Robert Beckley, had been on the staff in the eighteen-fifties and had designed the Kew self-recording meteorological instruments, which became almost as famous as the Observatory itself.

That Whipple had outstanding ability as a mathematician his university career had given evidence, and throughout his life he maintained his interest in mathematics; but he was also a physicist of no mean order, and the physical problems of meteorology, or rather geophysics, were entirely congenial to him. Whipple was not by nature original; but if in his reading or in conversation he came across a mathematical or physical problem he would devote time and energy to its solution. In this way seismology, atmospheric electricity and meteorological optics with their innumerable concrete problems interested him immensely and he became an authority on all these subjects. It was the exhibition by Sir Napier Shaw at the British Association meeting in Dublin of a diagram showing unexplained pressure waves on a microbarograph record which led to his outstanding paper on the great Siberian meteor, and it was the audibility in England of gun-fire on the Western Front during the War of 1914–18 which led directly to his major work on the transmission of sound, which has given us so much information about the temperature of the upper atmosphere. Practically the whole of Whipple's numerous publications deal with problems of this nature. Whether interest in such matters to the exclusion of more fundamental problems is in itself a good or a bad trait I am not prepared to say; but it played a great part in Whipple's success at Kew. Instead of being absorbed in his own investigations he took a personal interest in the work of the young men of science working under him, leading and helping them without any thought of credit to himself. The consequence was that the staff at Kew produced during Whipple's control a series of papers on seismology and atmospheric electricity which are of fundamental importance, and of which he and the Meteorological Office had every reason to be proud. With the passing of Dr. Chree, Kew Observatory ended an epoch of geomagnetic research; with Dr. Whipple commenced an epoch of research in seismology and atmospheric electricity which will be equally remarkable and has already enhanced the great reputation of Kew Observatory.

Whipple served on the National Committee for Geodesy and Geophysics of the Royal Society and was one of the British delegates to the International Geophysical and Geodetic Conference which met in Washington in September 1939. For a number of years he was chairman of the Seismological Committee of the British Association. He served on the Council of the Royal Meteorological Society and was president in 1937 and 1938. From 1930 until 1932 he was a member of the Board of the Institute of Physics.

From all this it will be seen that Whipple was an able man of science who was always ready to help and serve others; it is therefore not surprising that his death is felt in a very wide circle of friends. His wife died in 1926, as the result of a motor accident, and he leaves one son, who is following the scientific traditions of the Whipple family.

G. C. SIMPSON.

Dr. G. T. Bennett, F.R.S.

IN Dr. Geoffrey Thomas Bennett, who died after an operation on October 11, Cambridge loses one of her most characteristic sons: able in diverse ways, conscientious and thorough in all he was willing to undertake, and, for the most part, conservative in his scientific interests.

Born in London on June 30, 1868, he was at University College School, under Mr. H. W. Eve, and became in due course a scholar of St. John's College, Cambridge. Even then, the finish of the style of everything he wrote was remarked. In 1890 he was the senior wrangler, with distinction also in the second part of the Mathematical Tripos in 1891. It was in 1890 that Miss Fawcett, who, I believe, afterwards gave herself to the service of education in London, under the L.C.C., was placed above th senior wrangler. Soon after Bennett's consequen election to a fellowship at St. John's College, h followed a precedent set by A. G. Greenhill, an became mathematical lecturer and fellow at Emmanuel College. Here he continued to live, in room increasingly in tune with the rising style of amenit in Cambridge, and for many years, until his death had presided, as senior fellow, at the College dinner

Until after the War of 1914–18, mathematica lectures in Cambridge were organized for groups o colleges separately, and Bennett would lecture fo the group of which Emmanuel was part, possibly a enigma for some of his hearers; and he offered besides, an algebraical lecture on line-geometry ope to the whole University. His masterly instinct fo the geometry of mechanism was doubtless a bond o union with James Bennet Peace, who had graduate in 1887 from Emmanuel College, then teaching i the Engineering School (afterwards secretary of th Syndics of the University Press). In the afternoon he would often be seen sallying out on his summe or winter bicycle (according to the season), for whic the gearing had been arranged from a formula h gave to the cycle-agent, G. B. Howes. In the evenings he would often be found at the Universit concerts, and you would learn on inquiry that h had been giving attention to the mathematic aspects of music.

During the War of 1914–18 Bennett was for som time one of the party engaged, at Whale Island, i research in anti-aircraft gunnery; and passed to th gyrostatic compass department of the Admiralty a Slough, where he continued until after the armistice one remembers his characteristically trenchant remarks in regard to English knowledge of this compass. Since about 1920 he had withdrawn fro any overt connexion with the mathematical scho at Cambridge; but his touch could be recognize in various disclosures of his continuing interest mathematical curiosities of many kinds, includi models, of which he encouraged a fine collection Emmanuel College, and boomerangs. The late Maj MacMahon, for example, in his painstaking work regard to the regular division of the plane, was close touch with Bennett; and his help is ackno ledged in a certain striking book on school algeb It is to be expected that his drawers, when explore will bring many interesting mathematical results light.

In 1892, in more halcyon days than these, Cayl presented to the Royal Society a paper of 150 quar pages, devoted to the investigation of the primiti roots of a composite modulus (complex as well real). This was presumably developed from the ess he wrote for the Smith's Prize two years after h degree, and would amply suffice to establish h status as a mathematician. He became a memb of the London Mathematical Society in that yea of that Society he was later (1908–11) on the Counc and secretary during 1915–16. He became a fello of the Royal Society in 1914, and served on i council during 1936–38. At the time of his death was a fellow of University College, London.

The evidence of his interest in the kinematical que tions, in which he was superlative, may be indicat by reference to several of his published papers. In t *Philosophical Magazine* for June 1905, he wrote historical note in regard to the parallel motion marked by Sarrut, in 1853, giving a drawing of t mechanism employed. This seems not to be mention the enthusiastic lecture on "The Mechanical Con-ersion of Motion" given by Sylvester to the Royal nstitution in 1873, which begins with the Peaucellier ell of 1864. In the *Proceedings of the London Mathe-atical Society* we find "The Composition of Finite isplacements and the Use of Axodes" (1910), Deformable Octahedra" (1911), "The Skew Iso-ram Mechanism" (1913), and later, "The Three-bar extic Curve" (1920). But a more abstract paper of 910 is on the double six of lines on a cubic surface; an appendix to this he suggests a diagram, to hich he returns in 1911, for representing all the nes; this is in fact a graphical form for Steiner's set three complementary systems (1856), to which he oes not refer.

In a university which accepts the double task of ving instruction and care to all who are working r its examinations, and of fostering a lively interest the development of knowledge, many of the best rains among the teachers will be drawn, by loyalty or discipline, into the former task; and those who feel the importance of the latter may have a hard struggle. It is one of the complaints one has so often heard about some of the provincial universities. In the comparatively easier circumstances at Cambridge, one may say that Bennett made a wise compromise. The writings which he has left will remain as evidence of his great power and ability.

H. F. BAKER.

WE regret to announce the following deaths:

Sir Robert Falconer, K.C.M.G., president of the university of Toronto, aged seventy-six.

Prof. I. Traube, formerly of the Technische Hochschule, Berlin, and recently of Edinburgh, a well-known physical chemist and a pioneer in the field of surface chemistry, aged eighty-four.

Prof. Einar Lönnberg, the well-known Swedish geologist, died on November 21, 1942, and not on October 21, 1943, as stated in NATURE of November 6.

NEWS and VIEWS

oyal Society: Medal Awards

HIS Majesty the King has been graciously pleased approve the recommendations made by the ouncil of the Royal Society for the award of the o Royal Medals for the current year as follows: Sir Harold Spencer Jones, Astronomer-Royal, for s determination of the solar parallax and of other ndamental astronomical constants; to Dr. E. B. iley, director of H.M. Geological Survey, for his stinguished contributions to the knowledge of ountain structure and his studies on the tectonics vulcanism.

The following awards of medals have been made the president and Council of the Royal Society: pley Medal to Sir Joseph Barcroft, emeritus pro-ssor of physiology in the University of Cambridge, his distinguished work on respiration and the spiratory function of the blood; Davy Medal to of. I. M. Heilbron, professor of organic chemistry the Imperial College of Science and Technology, ndon, for his many notable contributions to organic emistry, especially to the chemistry of natural oducts of physiological importance; Sylvester dal to Prof. J. E. Littlewood, Rouse Ball professor mathematics in the University of Cambridge, for mathematical discoveries and supreme insight in analytical theory of numbers; Hughes Medal to of. M. L. E. Oliphant, Poynting professor of ysics in the University of Birmingham, for his tinguished work in nuclear physics and mastery methods of generating and applying high potentials.

tirement of Prof. O. T. Jones, F.R.S.

THE retirement of Prof. O. T. Jones from the oodwardian professorship of geology at Cambridge September 30 took many of his friends by sur-se, so little sign did he show of his approach to age limit set by the University Statutes. He nt to Cambridge from Manchester in 1930, well ed by his researches in Wales to foster that interest Lower Palæozoic stratigraphy and physiographical oblems which has long been associated with the mbridge school of geology. In this work he was prodigal of personal effort, and the intense fervour with which he threw himself into unravelling the complexities of 'slumping' in the Silurian rocks of Denbighshire is not likely to be forgotten by his staff and students of that time. By no means, however, did he limit himself to these fields, but continually found fresh interests to expound in which his insight seldom failed to bring out new points of capital importance. Indeed his tenure of the chair will be notable for its encouragement of interest in allied subjects; he established a close liaison with experimental geophysics and he was equally ready to collaborate with botanists and archæologists over the problems of the Fenland and Breckland of East Anglia, and with engineers in the laboratory study of stressed rocks.

That Prof. Jones's broad outlook was not limited to research was shown by the incorporation of practical work on sediments into the elementary geological course at Cambridge, with the establishment of a special laboratory under Mr. Maurice Black. Nor was it geographically circumscribed; in particular, his intercourse with the United States on Lower Palæozoic and geophysical problems, especially through the collaboration of Prof. R. M. Field of Princeton University, should continue to bear fruit in promoting scientific amity between the two shores of the Atlantic. Though war sadly depleted his department of students, it was quite unable to quell his determination to carry on field-work, and it is confidently hoped that his years of retirement will see the publication of further important research on the Lower Palæozoic of his own country of Wales.

Abraham Colles (1733–1843)

NOVEMBER 16, 1843, marks the centenary of the death of Abraham Colles, the eminent anatomist and surgeon of Dublin. He was born in 1773 at Milmont, near Kilkenny, and received his medical education at the University of Dublin, where he obtained his diploma at the Royal College of Surgeons in Ireland in 1795. He afterwards went to Edinburgh, where after two winter sessions he became M.D. He then made a journey, most of the way on foot, to London, where he made the acquaintance of Sir Astley Cooper, whom he assisted in his work on hernia and first became impressed with the inefficiency of the older modes of teaching anatomy. In 1797 he returned to Dublin and set up in practice. Two years later he commenced clinical teaching and also lectured on surgery in his private rooms. In 1804 he was appointed professor of anatomy and surgery at the Royal College of Surgeons in Ireland and held that post for thirty-two years. He was also surgeon to Steeven's Hospital, and was twice president (in 1802 and 1830) of the Royal College of Surgeons in Ireland. Selections from his works consisting chiefly of "Practical Observations on the Venereal Disease", in which he maintained that syphilitic children nursed at the breast often infect wet nurses but never their own mother—an observation afterwards known as Colles's law—appeared in the New Sydenham Society's publications in 1881 under the editorship of Robert McDonnell. His name has also been attached to a fracture of the lower end of the radius, which he described in 1814 in the *Edinburgh Medical and Surgical Journal.*

Theodor Engelmann (1843–1909)

THEODOR WILHELM ENGELMANN, an eminent German physiologist, was born at Leipzig on November 14, 1843, the son of a well-known publisher. He received his medical education at Jena, Leipzig, Heidelberg and Göttingen, and qualified at Leipzig in 1867. Directly after qualification he became assistant to Donders at the Physiological Institute at Utrecht, where he was appointed professor of general biology and histology, and succeeded Donders in the chair of physiology in 1888. In 1897 he succeeded Du Bois-Reymond as professor of physiology at Berlin, where he died on May 20, 1909. His most important work was the discovery of the cones and pigment cells of the retina. Besides studying the mechanics and thermodynamics of muscular contractions, he published works on ciliary movement (1868), spectrophotometric observations and an obituary of Helmholtz (1897). He was also co-editor of *Archiv für Physiologie.* He was well known to physiologists in Great Britain, where he was elected an honorary member of the Physiological Society in 1898. He was elected an honorary member of the American Physiological Society in 1904.

Plans for International Trade

UNDER the title "New Plans for International Trade", the Institute of Statistics, Oxford, has issued a Supplement to its Bulletin (No. 5, Vol. 5) reviewing the principles embodied in the proposal of the British Treasury for an International Clearing Union and that of the American Treasury for an International Stabilization Fund. An introductory paper by the editor points out that international trade exists because some goods can be produced relatively cheaper in some countries than in others, and the aim of an international currency plan must be to lay down a code of rules which countries agree upon and can be relied upon to apply in international trade and finance in different circumstances. The test questions are : (1) Are adequate provisions made for furnishing each country with liquid reserves for restarting international trade after the disruptions of the War and pre-war periods, as a means of enabling all countries to partake in international trade and reap the benefits of an exchange or loan of goods ? (2) How can we prevent countries from becomin illiquid again ? (3) How can we keep check upo and regulate short-term borrowing and lending, they are a disruptive element ? (4) How can w make an international system workable and com patible with any form of social-economic organizatio and any internal policy which member countri might wish to adopt ? (5) Can we introduce a stead expansionist force into international trade, whic would neutralize, or, if necessary, over-compensat the effects of restrictionist policies of some memb States on the rest of the trading community ?

Discussing the British plan, which purports t exert pressure on any country whose balance of pay ments with the rest of the world is departing fro equilibrium in either direction, E. F. Schumach states that the plan aims at more than equilibriu but does not fully face the issues of exchange contro He concludes that it would create internation liquidity on a generous scale—with all that th implies for the freedom and growth of internation trade—and that it is imbued with a spirit of expansio and is groping, though not very successfully, for way and means to create an international monetar mechanism favourable for expansion. The America plan does not seem to offer a workable system. It principal defect is a quantitative one. Even if th Stabilization Fund were considerably enlarged, ther would remain the difficulty that the Stabilizatio Fund technique itself imposes a more or less rigi maximum limit upon individual surpluses.

In the following paper, M. Kalecki and E. F Schumacher propose an amendment to the Britis plan in which an orderly supply of purchasing powe to deficit countries through long-term lending by th International Investment Board is made possibl The concluding paper, by T. Balogh, on "The Foreig Balance and Full Employment", examines furthe the question of how any single country can b enabled to maintain stability at full employment i a world system in which unemployment or inflatio exists in other countries.

Dehydration of Food by Radio-Frequency Energy

THE Industrial Electronics Division of the Feder Telephone and Radio Corporation, co-operating wit the Office of the Quartermaster-General of the Unite States Army, has developed a process of dehydratin food by means of radio-frequency energy. The pro cess is described briefly by Vernon W. Sherman i a recent article (*Elec. Comm.*, **21**, No. 2; 1943 The electronic dehydration method not only mak it possible to remove 99 per cent of the moistu content but it also permits this high degree of d hydration after the vegetables have been compress into a small block or briquette 6 in. × 3 in. × ¾ i Compression of vegetables prior to total dehydrati is an unprecedented procedure, other processes r quiring exposure of as much of the vegetable surfa as possible to facilitate evaporation. With all b one per cent of the moisture removed, it is possib to pack all types of dehydrated vegetables in seal containers and transport them to any part of th world without danger of decomposition. The leng of time vegetables may be kept in good conditi increases very greatly as the moisture conte approaches one per cent. Evidence now indicat that vegetables dehydrated by the electronic meth will not deteriorate over a period of one to two yea even in hot, humid climates.

Vegetables reconstituted after electronic dehydra-on may be cooked and served in the same way as esh vegetables. Reconstitution is accomplished by aking the vegetables in water. They then return to eir original colour and consistency and retain their ormal taste and aroma. The vitamin content of ectronically dehydrated vegetables is especially high, e apparently to the much shorter processing time. he exact method of dehydration cannot be dis-osed at present. Briefly, however, 80 per cent of e moisture is removed by conventional methods, aving the vegetables pliable but without formation 'case hardening'. The vegetables are then com-essed into bricks and the remaining moisture is moved electronically, after which they are ready be wrapped in paper, wax coated, packed and ipped. The whole procedure is well adapted to tomatic straight line production. Laboratory sults show that one pound of water may be re-oved electronically with less than one kWh. of ergy, a figure which is economically good in com-arison with other methods. In addition to vege-bles, dried whole milk also has had its moisture ntent reduced electronically from two per cent to e per cent. This small difference makes it possible ship dried whole milk without danger of its butter t content becoming rancid. Unlike dried skim milk, ied whole milk can be reconstituted to be as latable and nutritious as fresh milk. Apart from e importance of this electronic dehydration achieve-ent, the process represents another of the many tgrowths of fundamental research and develop-ent in industry. Electronic dehydration of food-uffs was undertaken by the Federal Telephone and adio Corporation as a co-operative and non-munerative project to aid in the war effort.

ecent Advances in Public Health Measures

FROM the *Fight Against Disease*, 31, 1943, issued y the Research Defence Society, we learn that six ti-vivisection societies reported in the last pre-war ar an income of more than £50,000. The Research efence Society, on the other hand, got along gorously in 1942 on about £500. Its report for 42 gives interesting details about the prevention a wide outbreak of smallpox when it appeared in otland in May 1942. Some of us who had to pass rough Glasgow in July of that year remember well e encouraging spectacle of the people crowding to e vaccination centres. About 500,000 people were ccinated and by July 31, thirty days after the ccination campaign had begun, the last case of allpox was reported. The report also deals with e remarkable results of immunization against phtheria. There must be few intelligent people ho will refuse their children this inestimable benefit. any are still disposed to do so, they should read T. Russell's report, published by the Medical esearch Council, on the epidemiology of diphtheria ring the last forty years.

The Ministry of Health, Ministry of Information nd Central Council for Health Education send us mples of the publicity material issued by them r use in the campaign against diphtheria. Sir ilson Jameson calculates that diphtheria kills meone in Great Britain every three or four hours d every twenty minutes sends a child to hospital. he number of children who have been protected is ot enough. Children under five are most likely to iffer. It is astonishing that parents can still fail to take their children to receive this safe, simple treatment, obtainable free through any medical officer of health. It should be obtained now, before the winter comes.

The Medical Research Council sends us another valuable memorandum (War Memorandum No. 10) entitled the "Medical Use of Sulphonamides". This deals with the chemistry, pharmacology, dosage, toxicity and supply of these drugs and with the treatment of specific infections with them. They have been given so many names that the lists here given of the alternative names of each compound will help to prevent confusion. Appendixes deal with the estimation of the concentration of sulphonamides in the body fluids, with tests for sulphonamide-resistance in bacteria and with the sterilization of sulphanilamide powder.

Authority in Medicine

IN the Linacre Lecture delivered at St. John's College, Cambridge, on May 6, 1943, Prof. Major Greenwood, after a graceful tribute to previous lecturers including Sir Thomas Watson, Sir Humphry Rolleston, Sir George Newman and Dr. W. W. C. Topley, dealt at length with the doctrine of Galen, with whom Linacre was familiar, and particularly his work on epidemiology, general hygiene and medical psychology. Prof. Greenwood regards Galen's epidemiological influence as bad because he overrated the creative power not of Nature but of his own intelligence, and never considered alternative hypotheses as was done by John Graunt fifteen hundred years later. Galen's work on personal hygiene, which Prof. Greenwood regards as the most readable of his books, contains an admirable description of practical dietetics, physical training and the Horation philosophy of life. As regards medical psychology, according to Prof. Greenwood, Galen was in advance of any medical writers of the Renaissance. Passing on to the subject of experimental epidemiology, in which he was associated with Dr. Topley for more than fifteen years, Prof. Greenwood points out that in acute infectious diseases like typhus pure laboratory work has created an applied science of immunology which owes nearly everything to the experimental method. The lecture ends with an encomium of the late Sir Walter Fletcher, secretary of the Medical Research Council, of whom he says that "he fought for and secured a scientific freedom in state-aided medical research".

Archæological Research in Ulster

IN 1935 the Government of Northern Ireland agreed to pay 60 per cent of the wages of unemployed labourers engaged for the purpose of archæological excavation, up to a total sum of £500. Later the percentage was raised to 80. This method of dealing with the then acute problem of unemployment was to some extent copied from that already in operation in the Irish Free State. As a result, much valuable excavation was undertaken in 1935 and succeeding years, and important information has come to light. More particularly have the various museums and archæological societies, which have taken advantage of the opportunity, concentrated on the study of the North Irish megalithic monuments. Ireland's geographical position is such that the island was a very important area in the days when the megalith builders were wandering about parts of western Europe. Northern Ireland has its full share of these monuments. Then again, Northern Ireland has yielded important Mesolithic industries, the study of which is still incomplete. Nor must relics of later periods be forgotten, and crannogs, earth-forts, etc., have received attention. Further, it has been realized that excavation without subsequent publication is of little worth.

Naturally, much of the new information has found its way into the older well-known archæological journals and proceedings, but special reference must be made to the *Ulster Journal of Archæology*, which has just published its sixth volume, containing an account by the editor of the archæological achievement of the last ten years. The reader will certainly find this publication eclectic in its interests, and much curious and interesting information on subjects ranging from prehistoric to modern can be culled from its pages. It is to be regretted that England, during the periods of acute unemployment, did not follow the lead given by Ireland. Of course, here, as indeed in Ireland too, museums and local archæological societies make grants for the purposes of excavation. But direct Government aid of the kind mentioned above gives an immense fillip to such work, and there is a direct return to the body politic, which is scarcely the case when the money is merely spent in 'doles'. The Irish method at least means that more becomes known of the country's past.

Labour in the Building Industry

A RECENT broadsheet (No. 212) issued by Political and Economic Planning contains a close analysis of the organization of the labour force in the building industry in Great Britain, nationally, on the site and in the trade unions, which represents part of a wider study of industrial relations which was undertaken before, but was interrupted by, the War. The analysis covers all sizes and types of unit, from the very large firms down to the small firms and their groups. It gives a clear picture of the organization of labour on the site including the organizing personnel, the recruitment of foremen and the part played by the trade unions, as well as of the organization of labour in the unions, including the federation branch, the executive committee, the National Joint Council, the rates of wages and payment by results. In the post-war period the latter question will be linked with the questions of prefabrication and of new and more flexible types of training, and the essential changes of practice are unlikely to be secured without a sense of urgency and without Government intervention which can be visualized only as part of a great plan of guaranteed employment for the building industry. With guaranteed employment all sorts of technically desirable changes may well become more acceptable, but the goodwill of the trade unions is indispensable, and this can only be obtained by full and frank consultation, and by democratic discussion both at the national level, in the localities and on the site.

Scientific Societies of North America

THE U.S. National Research Council has produced a fourth edition of its "Handbook of Scientific and Technical Societies and Institutions of the United States and Canada" (Bull. 106, Jan. 1942. Washington, D.C.: National Academy of Sciences). This well-bound volume of 389 large pages contains information relating to 1,269 bodies in the United States and its dependencies, and 143 in Canada, which "contribute to the advancement of knowledge through their meetings, publications or oth resources", and are included in the wide fields natural sciences, technology and more general orga izations supporting scientific research. Agencies the Federal Government, organizations directly co trolled by universities, bodies which act throug grants rather than direct by conducting research, an industrial research laboratories are excluded. In eac case there are given the name and address of th organization, the chief officers, a brief history, it objects, particulars of membership, meetings, researc funds and medals, and serial publications. The dat have been compiled from information received fro the bodies concerned. The entries are arranged alph betically in two sections, one for the United Stat and one for Canada. There are subject and personn indexes for each section. The only comparable pu lication in Great Britain is the "Official Year-Boo of the Scientific Societies of Great Britain and Ir land", published by Messrs. Charles Griffin and Co Ltd., for many years, but discontinued since th beginning of the War. Such reference books ar of much value in the library and elsewhere.

Rare Scientific Books

CATALOGUE 8 (Spring 1943) issued by Schuman' 20 East 70th Street, New York, contains 485 item the great majority of which are of medical interes but including a number of non-medical scientifi works as well. Special mention may be made of th following: several works by Vesalius including th third edition of the "Fabrica", the first edition Casserio's "Tabulæ Anatomicæ" (1627), Fallopio' "Institutiones Anatomicæ" (1585), the first editio of Acosta's "Herbal" (1578), Cesalpino's "D Plantis" (1583); Fracastor's "Opera Omnia" (1555 the first edition of Conrad Gesner's "Surgical Tracts (1516–65), Hans Sachs' folk poem (*c.* 1550), the firs edition of Guido Guidi's work on surgery (1544), th first edition of Cockayne's "Leechdoms" (1864–66 the first edition of Morgagni's "De Sedibus et Caus Morborum" (1761). The non-medical works includ the first edition of Goethe's "Metamorphose d Pflanzen" (1790), the first edition of Lyell's "Ge logical Evidence of the Antiquity of Men" (1863 the first edition of Newton's "Optics" (1704) an the first edition of the "Origin of Species" (1859 and Francis Hauksbee's "Physico-Mechanical Exper ments on various Substances" (1709).

Announcements

A SPECIAL meeting to commemorate the life an work of Nikola Tesla will be held at the Institutio of Electrical Engineers on November 25, at 3 p. At the meeting a lecture, with examples of Tesla' experimental work, will be delivered by Dr. A. P. Fleming, director and manager, Research an Education Departments of Messrs. Metropolita Vickers Electrical Co., Ltd.

IN reviewing Prof. J. C. Slater's "Introduction Chemical Physics" in NATURE of October 30, p. 48 the price of the book quoted was that of the time issue, namely, 33*s.*; we are informed by the McGraw Hill Book Co., Inc., that the current price is 35*s.*

ERRATUM. In NATURE of November 6, p. 53 col. 2, line 1, for "flies is not due to mechanic inability to reach the goal", read "flies is due mechanical inability to reach the goal".

Recognition of *Rh* Genotypes in Man

In a recent communication, two of us[1] described a serum which we think discloses the genotype of half the persons who are homozygous for the blood group factor *Rh*. This serum, *St*, agglutinates the red cells of about 80 per cent of people, including the 15–16 per cent who are *Rh*-negative and all the 48 per cent who are heterozygous, *Rhrh*. It fails to react with 20 per cent, all of whom must be homozygous *RhRh* and be about half the total number of homozygotes (about 38 per cent of all people).

It is certain that multiple allelomorphs of the *Rh* gene occur, and to begin with three may be assumed, Rh_1, Rh_2 and *rh*. We suggested that *St* negative (*St*−) people are Rh_1Rh_1. If *St* fails to agglutinate the cells of persons with the Rh_1 gene it must react with all other frequent allelomorphs, Rh_2 and *rh*, in order to make up its 80 per cent of positive reactions.

Recently we have found in the serum of the mother of an erythroblastotic infant a different type of rare anti-*Rh* agglutinin. This serum, which we call *K*, is positive with about 30 per cent of the population, and Dr. C. V. Harrison has sent a second serum, *J*, which gives identical results. We have used *St*, *K*, *J* and normal anti-*Rh* sera to examine the blood of 281 unselected donors (205 at Cambridge and 76 at Sutton) as well as members of families we were investigating for the *Rh* factor in connexion with erythroblastosis fœtalis. The results from the two unselected groups together are:

	St+	*St*−		*KJ*+	*KJ*−		*KJ*+	*KJ*−
Rh+	174	52	*Rh*+	84	142	*St*+	83	146
Rh−	55	0	*Rh*−	2	53	*St*−	3	49

It is seen that (*a*) *Rh*− blood is *St*+; (*b*) *Rh*− blood is nearly always *KJ*−; (*c*) *St*− blood is nearly always *KJ*−. Apart from the five exceptions, it seems that *KJ* can react neither with Rh_1 nor *rh*, and must, therefore, react with Rh_2 to achieve its 30 per cent of positives. (The estimated frequency of the genotypes containing Rh_2 is very near to 30 per cent.) Besides the five exceptions in the 281 unselected bloods, two of them *Rh*−*St*+*KJ*+ and three *Rh*+*St*−*KJ*+, a further example of each type was found in the 139 family samples.

We suppose that the genes so far discussed cause the following reactions:

		Antisera		
		Rh	*St*	*KJ*
	Rh_1	+	−	−
Genes	Rh_2	+	+	+
	rh	−	+	−

If this is true, it follows that Rh_1rh blood must be *Rh*+*St*+*KJ*−. No combination of two of these allelomorphs can make either *Rh*−*St*+*KJ*+ or + − +. The first case, − + +, could be explained by the presence of a rare gene reacting with *KJ* and not with *Rh*; we may provisionally call this Rh_x. Since it is so rare, it seems certain that in our three examples of this type of exception the gene is not in the homozygous state (for if it was present here in the homozygous state it can be calculated that the frequency of Rh_xrh, − + +, would be about 1 in 15 of all persons). The genotype cannot be Rh_1Rh_x or Rh_2Rh_x, since both of these would be *Rh*+ (Rh_xRh_y, see below, would also be much too rare). The genotype must therefore be Rh_xrh. American workers have described anti-*Rh* sera which react with 2 per cent of people who are *Rh*− with the anti-*Rh* sera most commonly found. It is possible that such a serum would be positive with this genotype Rh_xrh. Although Rh_xrh will be *St*+ by virtue of its *rh* gene, there is evidence that Rh_x also reacts with *St*. If *St* serum is titrated with *rhrh* blood and Rh_1rh blood, the red cells representing the double dose of the *St*-active *rh* gene agglutinate at a much higher dilution (eight times on the average) than do the Rh_1rh cells representing a single dose of the *St*-active gene. Two of our examples of Rh_xrh have been titrated and they are both at the top of the double-dose class.

If the gene Rh_x does react with *St*, as seems likely, then to explain the second class of exception, + − +, a further allelomorph Rh_y which is *St*−*KJ*+ must be postulated. The genotype of the four exceptions of this kind cannot with reasonable probability be Rh_yRh_y. It cannot be Rh_yrh, Rh_2Rh_y or the rare Rh_xRh_y, for all these would be *St*+. This leaves only Rh_1Rh_y. It cannot be said at this stage whether Rh_y is *Rh*+, for Rh_1 may be wholly responsible for the *Rh*+ reactions of these four bloods; no help is given by titration, for anti-*Rh* does not make such a distinction as does *St*. The extended scheme is:

		Antisera		
		Rh	*St*	*KJ*
	Rh_1	+	−	−
	Rh_2	+	+	+
Genes	Rh_x	−	+	+
	Rh_y	?	−	+
	rh	−	+	−

Only a rough estimate of the frequencies of Rh_x and Rh_y can be made since the total figures are small for such infrequent genes. For what they are worth they may be derived:

$$Rh_xrh = 0{\cdot}007 \text{ and } Rh_x = \frac{0{\cdot}007}{2 \times \text{frequency of } rh} = 0{\cdot}009 \text{ or } 0{\cdot}9 \text{ per cent}$$

$$Rh_yRh_1 = 0{\cdot}011 \text{ and } Rh_y = \frac{0{\cdot}011}{2 \times \text{frequency of } Rh_1} = 0{\cdot}013 \text{ or } 1{\cdot}3 \text{ per cent}$$

The frequency of Rh_x must be deducted in calculating that of *rh*, and the frequency of Rh_y deducted similarly in calculating Rh_1. The proportion of *Rh* negatives among persons examined by us is 722 out of 4,618, or 15·63 per cent. Taking the square root, we have 39·5 per cent as the combined gene frequency of *rh* and Rh_x. Using the frequency estimated above for Rh_x this gives

rh	38·6 per cent
Rh_x	0·9 ,, ,,

Similarly, the proportion of *St* negatives observed is 97 out of 499, or 19·44 per cent. Taking the square root, we have 44·09 per cent as the combined gene frequency of Rh_1 and Rh_y, giving

Rh_1	42·8 per cent
Rh_y	1·3 ,, ,,
leaving Rh_2	16·4 ,, ,,

If we group together as "the rest" all the genotypes which we cannot recognize serologically, we can compare observed and expected frequencies:

	+ − −	− + −	+ + −	− + +	+ − +	+ + +
	Rh_1Rh_1	*rhrh*	Rh_1rh	Rh_xrh	Rh_1Rh_y	The rest
Observed per cent	17·4	18·9	33·1	0·7	1·1	28·8
Expected per cent	18·3	14·9	33·0	0·7	1·1	31·9

The close fit is good confirmation that the genotypes do react with these three sera as we suppose. The fit of Rh_1rh is particularly important as the expectation could be calculated before *KJ* serum was discovered. Significant also are the children of matings Rh_1Rh_1 × *rhrh*, since all must be Rh_1rh. We have examined nine such families with sixteen children all

$Rh+St+KJ-$. The probability that all sixteen would be *KJ* negative by chance is $0{\cdot}63^{16} = 0{\cdot}0006$ (the chance of an $Rh+$ person being $KJ-$ is 0·63). Twenty-five families so far examined have shown no discrepancies. By the use of normal anti-*Rh*, *St* and *KJ* sera the genotypes Rh_1Rh_1, Rh_1rh, $rhrh$, Rh_xrh and Rh_1Rh_y, 68 per cent of the total, can be recognized. This is of prognostic importance in families in which erythroblastosis fœtalis has occurred; and it should increase the usefulness of the *Rh* blood groups in linkage studies.

Since this work has been done, we have received a paper by Wiener and Landsteiner[2] giving frequencies for the genes Rh_1 48 per cent, Rh_2 16 per cent and *rh* 36 per cent. These frequencies were derived from the behaviour of sera quite different from *St* and *KJ*. In a personal communication at the same time, Wiener says that they now have papers in the press demonstrating six distinct allelomorphs. We are at present calling our fourth and fifth allelomorphs Rh_x and Rh_y, in the hope that a name and place is ready for them in Wiener's scheme.

Chemical Control of Mitosis

A CONNEXION between the mode of action of carcinogenic and of polyploidogenic reagents has frequently been postulated[1,2], but the crucial test of the induction of polyploidy in plants by a typical carcinogenic hydrocarbon has so far not been recorded. Patton and Nebel[3], for example, report that dibenzanthracene causes increase in the size of the prophase nuclei in the root tips of Zea, but state that no abnormality of mitosis could be observed. It was therefore with some surprise that we found recently on examining the root tips of rye seedlings, which had been growing in water containing crystals of 1.2.5.6 dibenzanthracene, a striking polyploidogenic effect. This did not occur in the control with water alone.

We repeated the experiment, but found only normal growth, and it was some time before we traced the reason for the first result. At that time we had also been working with organic mercury compounds such as are used for dusting seeds to prevent fungal attack. These compounds are crystalline solids, but some have an appreciable vapour pressure and even at room temperature give off a toxic vapour. This led us to suspect that the laboratory air may have been vitiated and we repeated the first experiment in an atmosphere which was in equilibrium with solid ethyl mercuric chloride. The result was precisely as in the first experiment, namely, definite chromosome doubling.

Further trials showed that a very dilute solution of ethyl mercuric chloride gave the same result and had the great convenience that the dosage could be controlled.
